38 | **Abstract.** Total alkalinity (A_T) and dissolved inorganic carbon (C_T) in the oceans are important properties to
39 | understand the ocean carbon cycle and its link with global change (ocean carbon sinks and sources, ocean
40 | acidification) and ultimately find carbon based solutions or mitigation procedures (marine carbon removal). We
41 | present an extended database (SNAPO-CO₂, Metzl et al, 2024d) with 24700 new additional data for the period
42 | 2002 to 2023. The full database now includes more than 67000 A_T and C_T observations along with basic
43 | ancillary data (time and space location, depth, temperature and salinity) in various oceanic regions obtained since
44 | 1993 mainly in the frame of French research projects. This includes both surface and water columns data
45 | acquired in open oceans, coastal zones, rivers and in the Mediterranean Sea and either from time-series or
46 | punctual cruises. Most A_T and C_T data in this synthesis were measured from discrete samples using the same
47 | closed-cell potentiometric titration calibrated with Certified Reference Material, with an overall accuracy of ± 4
48 | $\mu\text{mol kg}^{-1}$ for both A_T and C_T . The same technique was used onboard for underway measurements during cruises

49 conducted in the Southern Indian and Southern Oceans. The A_T and C_T data from these cruises are also added in
50 this synthesis. The data are provided in one dataset for the global ocean (<https://doi.org/10.17882/102337>) that
51 offers a direct use for regional or global purposes, e.g. A_T /Salinity relationships, long-term C_T estimates,
52 constraint and validation of diagnostics C_T and A_T reconstructed fields or ocean carbon and coupled
53 climate/carbon models simulations, as well as data derived from Biogeochemical-Argo (BGC-Argo) floats.
54 These data can also be used to calculate pH, fugacity of CO₂ ($f\text{CO}_2$) and other carbon system properties to derive
55 ocean acidification rates or air-sea CO₂ fluxes.

56

57 **1 Introduction**

58

59 The ocean plays a major role in reducing the impact of climate change by absorbing more than 90% of
60 the excess heat in the climate system (Cheng et al., 2020, 2024; von Schuckmann et al, 2023; IPCC, 2022) and
61 about 25% of human released CO₂ (Friedlingstein et al., 2022, 2023). In the last decade, the oceans experienced
62 a rapid warming, the year 2023 being the hottest since 1955 (Cheng et al, 2024). In the atmosphere the CO₂
63 concentration continues its terrific progressive rising, reaching 419.3 ppm in 2023 (a rate of +2.83 ppm yr⁻¹, Lan
64 et al 2024). In August 2024, the global atmospheric CO₂ concentration was already above 420 ppm. In the next
65 decade the oceans will continue to capture heat and CO₂, somehow limiting the climate change, but this oceanic
66 CO₂ uptake changes the chemistry of seawater reducing its buffering capacity (Revelle and Suess, 1957; Jiang et
67 al, 2023). This process known as ocean acidification has potential impacts on marine organisms (Fabry et al.,
68 2008; Doney et al., 2009, 2020; Gattuso et al., 2015). With atmospheric CO₂ concentrations, surface ocean
69 temperature and ocean heat content, sea-level, sea-ice and glaciers, the ocean acidification (decrease of pH) is
70 now recognized by the World Meteorological Organization as one of the 7 key properties for global climate
71 indicators (WMO, 2018). Ocean acidification is specifically referred in the SDG indicator 14.3.1 coordinated at
72 the Intergovernmental Oceanographic Commission (IOC) of UNESCO. Observing the carbonate system in the
73 open oceans, coastal zones and marginal seas and understanding how this system changes over time is thus
74 highly relevant not only to quantify the global ocean carbon budget, the anthropogenic CO₂ inventories or ocean
75 acidification rates, but also to understand and simulate the processes that govern the complex CO₂ cycle in the
76 ocean (e.g. Goyet et al, 2016, 2019) and to better predict the future evolution of climate and global changes
77 (Eyring et al., 2016; Kwiatkowski et al., 2020; Jiang et al., 2023). As the rate of change in ocean acidification
78 presents large temporal and regional variability, long-term observations are required. Weekly to monthly regular
79 resolution data are needed to better investigate the long-term change of the carbonate system in regions subject
80 to extreme events (e.g. tropical cyclones, marine heat or cold waves, rapid freshening, convection, dust events,
81 river discharges, etc....). In this context it is recommended to progress in data synthesis of the ocean carbon
82 observations that would offer new high quality products for the community (e.g. for GOA-ON, www.goa-on.org,
83 IOC/SDG 14.1.3, <https://oa.iode.org/>, Tilbrook et al., 2019).

84 In this work, following the first SNAPO-CO₂ synthesis product (Metzl et al, 2024a), we present a new
85 synthesis of more than 67000 A_T and C_T data, measured either on shore or onboard Research Vessels obtained
86 over the 1993-2023 period during various cruises or at time-series stations mainly supported by French projects.
87 Hereafter this new dataset will be cited as SNAPO-CO₂-v2. The methods, data assemblage and quality control

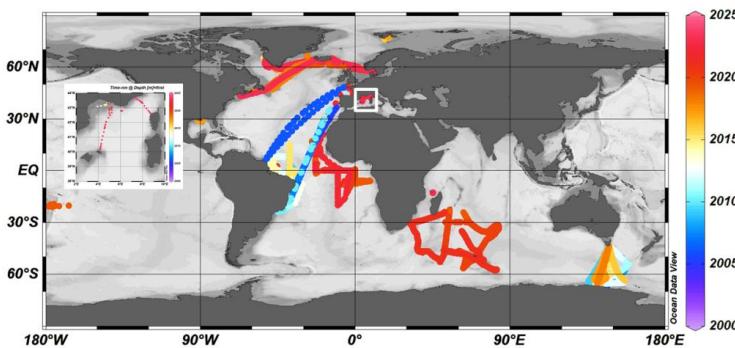

88 were presented in version V1. Here, we describe the new data added and discuss some potential uses of this
89 dataset.

90

91 **2 Data collections**

92

93 The time series projects and research cruises from which new data were collated are listed in Table 1
94 with information and references in the Supplementary file (Tables S1, S3 and S4). The sampling locations of
95 new data are displayed in Figure 1 (the location for all data presented in Figure S1). Sampling was performed
96 either from CTD-Rosette casts (Niskin bottles) or from the ship's seawater supply (intake at about 5m depth
97 depending on the ship and swell). Samples collected in 500 mL borosilicate glass bottles were poisoned with 100
98 to 300 μL of HgCl_2 depending on the cruises, closed with greased stoppers (Apiezon®) and held tight using
99 elastic band following the SOP protocol (DOE, 1994; Dickson et al., 2007). Some samples were also collected in
100 500 mL bottles closed with screw caps. After completion of each cruise, most of discrete samples were returned
101 back to the LOCEAN laboratory (Paris, France) and stored in a dark room at 4 °C before analysis generally
102 within 2-3 months after sampling (sometimes within a week). In this version we added data from samples that
103 were also returned to University of Perpignan or to University of La Réunion. In addition to discrete samples
104 analyzed for various projects conducted mainly in the North Atlantic, Tropical Atlantic, Mediterranean Sea and
105 coastal regions (Table 1), we complemented this second synthesis with A_T and C_T surface observations obtained
106 in the Indian and Southern oceans during the OISO cruises in 2019-2021 (Lesure et al., 2022; Metzl et al,
107 2022; data also available at NCEI/OCADS: www.nodc.noaa.gov/ocads/oceans/VOS_Program/OISO.html) and
108 MINERVE cruises in 2002-2018 (Laika et al, 2009; Brandon et al, 2022). The A_T and C_T measurements from the
109 MINERVE cruises were performed either onboard R/V Astrolabe or back in the laboratories (at LOCEAN
110 laboratory and at University of Perpignan).

174 3 Method, accuracy, repeatability and quality control

176 3.1 Method and accuracy

178 Since 2003, the discrete samples returned back at SNAPO-CO₂ Service facilities (LOCEAN, Paris),
 179 were analyzed simultaneously for A_T and C_T by potentiometric titration using a closed cell (Edmond, 1970;
 180 Goyet et al., 1991). The same technique was used at sea for surface water underway measurements during OISO
 181 and MINERVE cruises (indicated by * in Table 1). In the late 1980s the so-called “JGOFS-IOC Advisory Panel
 182 on Ocean CO₂” recommended the need for standard analysis protocols and for developing Certified Reference
 183 Materials (CRMs) for inorganic carbon measurements (Poisson et al., 1990; UNESCO, 1990, 1991). The CRMs

were provided to international laboratories by Pr. A. Dickson (Scripps Institution of Oceanography, San Diego, USA), starting in 1990 for C_T and 1996 for A_T , respectively. These CRMs were thus always available to us and used to calibrate the measurements (CRM Batch numbers used for each cruise are listed in the Supplementary file, Table S2). The CRMs accuracy, as indicated in the certificate for each Batch, is around $\pm 0.5 \mu\text{mol kg}^{-1}$ for both A_T and C_T (www.nodc.noaa.gov/ocads/oceans/Dickson_CRM/batches.html). The concentrations of CRMs we used vary between 2193 and $2426 \mu\text{mol kg}^{-1}$ for A_T and between 1968 and $2115 \mu\text{mol kg}^{-1}$ for C_T corresponding to the range of concentrations observed in open ocean water. In the Mediterranean Sea the concentrations are higher ($A_T > 2600 \mu\text{mol kg}^{-1}$ and $C_T > 2300 \mu\text{mol kg}^{-1}$) and in the coastal zones or near the Amazon River plume the concentrations were often lower than the CRMs ($A_T < 1500 \mu\text{mol kg}^{-1}$ and $C_T < 1000 \mu\text{mol kg}^{-1}$). Results of analyses performed on 1242 CRM bottles (different Batches) in 2013-2024 are presented in Figure 2. The standard-deviations (Std) of the differences of measurements were on average $\pm 2.69 \mu\text{mol kg}^{-1}$ for A_T and $\pm 2.88 \mu\text{mol kg}^{-1}$ for C_T . For unknown reasons, the differences were occasionally up to $10-15 \mu\text{mol kg}^{-1}$ (1.2% of the data, Figure S2). These few CRM measurements were discarded for the data processing. We did not detect any specific signal for CRM analyses (e.g., larger uncertainty depending on the Batch number or temporal drifts during analyses, Figure 2) but for some cruises the accuracy based on CRMs could be better than $3 \mu\text{mol kg}^{-1}$ (e.g. $< 3 \mu\text{mol kg}^{-1}$ for AMAZOMIX cruise using 6 Batches #197 and for MOOSE-GE 2022 using 19 Batches #204, or $< 1.5 \mu\text{mol kg}^{-1}$ for SOMLIT-Point-B in 2022 using 6 Batches #204).

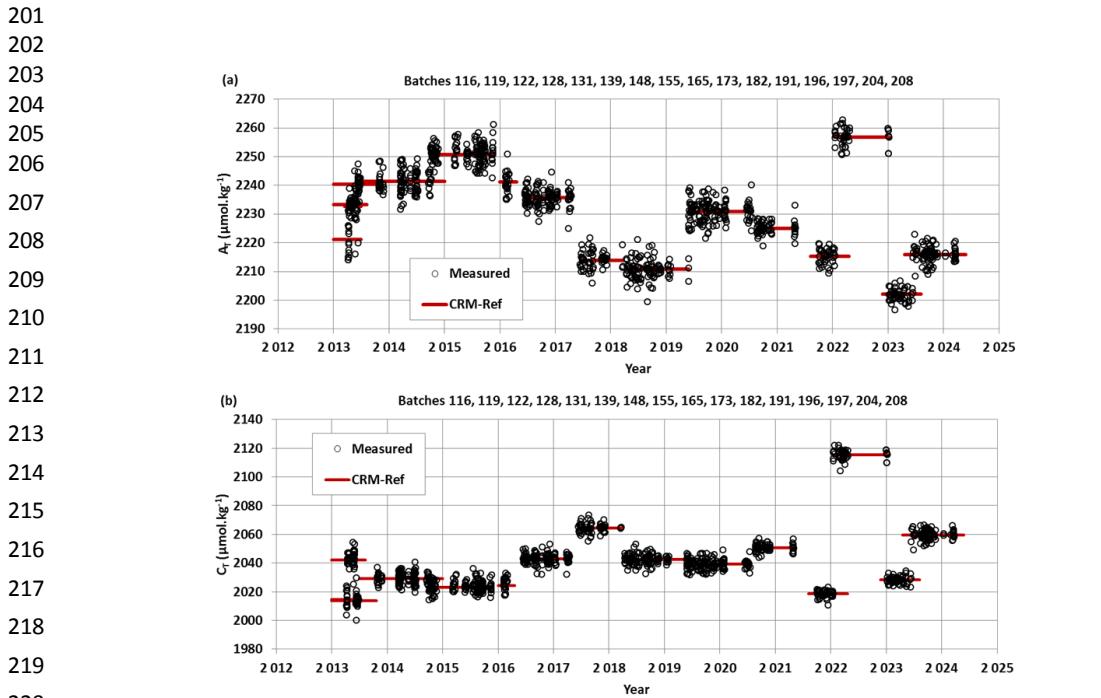

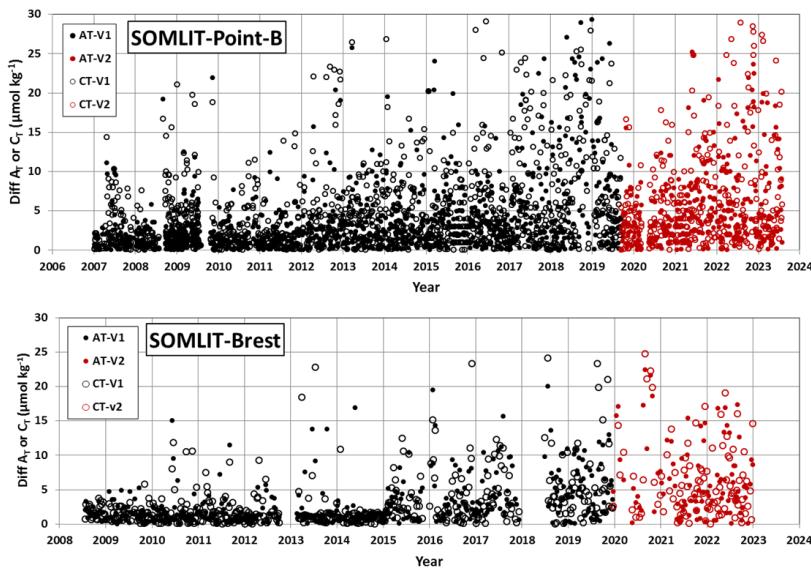

Figure 2: A_T (a) and C_T (b) analyses for different CRM Batches measured in 2013-2024. For these 1242 analyses the mean and standard-deviations of the differences with the CRM reference were $-0.11 (\pm 2.69) \mu\text{mol kg}^{-1}$ for A_T and $0.01 (\pm 2.88) \mu\text{mol kg}^{-1}$ for C_T .

227 **3.2 Repeatability**
 228

229 For some projects, duplicates have been regularly sampled (SOMLIT-Point-B, SOMLIT-Brest) or
 230 replicate bottles sampled at selected depths at fixed stations during the cruises (e.g. STEP, CARBODISS). In the
 231 first synthesis of the SNAPO-CO₂ dataset we showed the results from several time-series (SOMLIT-Point-B,
 232 SOMLIT-Brest and BOUSSOLE/DYFAMED). Here we present the results for the new data obtained at
 233 SOMLIT-Point-B in the coastal Mediterranean Sea and SOMLIT-Brest in the Bay of Brest (Figure 3). Results of
 234 A_T and C_T repeatability are synthetized in Table 2. For the OISO cruises conducted in 2019, 2020 and 2021 the
 235 repeatability was evaluated from duplicate analyses (within 20 minutes time) of continuous sea surface
 236 underway sampling at the same location (when the ship was stopped). Similarly to what was found for the CRM
 237 measurements (Figure S2), differences in duplicates are occasionally higher than 10-15 $\mu\text{mol kg}^{-1}$ (Figure 3) but
 238 most of the duplicates for all projects are within 0 to 3 $\mu\text{mol kg}^{-1}$. Compared to previous results (Kapsenberg et
 239 al. 2017; Metzl et al, 2024a), there are larger differences between duplicates at SOMLIT-B in 2019-2023 (up to
 240 30 $\mu\text{mol kg}^{-1}$, Figure 3) leading to relatively large Std around 5 and 6 $\mu\text{mol kg}^{-1}$ for both A_T and C_T (Table 2).
 241 The same was observed for duplicates at SOMLIT-Brest (Table 2). We do have not yet a clear explanation for
 242 this large Std although larger variability was observed in recent years, and the measurements were performed
 243 later after the sampling (e.g. more than 6 months for some samples during and after the COVID period). We will
 244 see that given the temporal variability of the properties this does not lead to suspicious interpretation for the
 245 seasonality or the trend analyses of these time-series.

264 **Figure 3:** Results of duplicate A_T and C_T analyses from the time-series SOMLIT-Point-B in the coastal
 265 Mediterranean Sea and SOMLIT-Brest in the coastal Brittany for the data in the SNAPO-CO₂-v1 dataset (black)
 266 and new data added in SNAPO-CO₂-v2 (red). The plots show differences in duplicates for both A_T (filled
 267 circles) and C_T (open circles). Standard-deviations of these duplicates are listed in Table 2.
 268
 269

270 **Table 2:** Repeatability of A_T and C_T analyses for cruises with duplicate analysis. The results are expressed as the
 271 standard-deviations (Std) of the analysis of replicated samples. Nb = the number of replicates for each Time-
 272 series or Cruise. For the OISO cruises the mean repeatability was obtained from measurements at the same
 273 location (when the ship stopped).

Cruise	Period	Nb	Std A_T μmol kg ⁻¹	Std C_T μmol kg ⁻¹	Reference
STEP	2017	3	0.7	2.8	Unpublished
CARBODISS	2018	10	6.72	5.71	Unpublished
SOMLIT-Point-B	2007-2019	1130	4.5	5.1	SNAPO-CO2-v1, (a)
SOMLIT-Point-B	2019-2023	321	5.2	6.2	SNAPO-CO2-v2, (a)
SOMLIT-Brest	2008-2018	404	3.1	3.4	SNAPO-CO2-v1, (a)

(a) See Figure 3 for the results of regular duplicates for time-series SOMLIT-Point-B, SOMLIT-Brest.

(b) Metadata and data available at www.nodc.noaa.gov/ocads/oceans/VOS_Program/OISO.html

296 **3.3 Assigned flags for quality control**

297 Identifying each data with an appropriate flag is very convenient for selecting the data (good,
 298 questionable or bad). Here we used 4 flags for each property (flags 2 = good, 3= questionable, 4=bad, and 9= no
 299 data) following the WOCE program and used in other data products such as SOCAT (Bakker et al., 2016) or
 300 GLODAP (Olsen et al., 2016; Lauvset et al., 2024). During the data-processing, we first assigned a flag for each
 301 A_T and C_T data based on the standard error in the calculation of A_T and C_T concentrations (non-linear regression,
 302 Dickson et al. 2007). By default, if the standard deviation on the regression is $> 1 \mu\text{mol kg}^{-1}$, we assigned a flag 3
 303 (questionable) although the data could be acceptable and then used for interpretations. Flag 3 was also assigned
 304 when salinity was doubtful or when differences of duplicates were large (e.g. $\pm 20 \mu\text{mol kg}^{-1}$). Flags 4 (bad or
 305 certainly bad) were assigned when clear anomalies were detected for unknown reasons (e.g. a sample probably
 306 not fixed with HgCl_2 or analysis performed late during the COVID issue). A secondary quality control was
 307 performed by the PIs of each project based on data inspection, duplicates, A_T /Salinity relationship, or the mean
 308 observations in deep layers where large variability in A_T and C_T is unlikely to occur from year to year.

309 An example for quality flag is presented for all data from the MINERVE cruises conducted in 2002-
 310 2018 in the Southern Ocean where clear outliers have been identified (Figure S3). For the MINERVE cruises in
 311 2002-2018 and a total of 12335 A_T and C_T analyses, 24 were identified as bad (flag 4), 978 for A_T and 971 for C_T
 312 listed as questionable (flag 3), and all others are considered as good data (flag 2, i.e. about 92%). For the
 313 MOOSE-GE cruises in 2021, 2022 and 2023 (new data in SNAPO-CO2-v2) and a total of 1373 A_T and C_T
 314 analyses, 2 were identified flagged as bad (flag 4), 38 for A_T and 33 for C_T listed as questionable (flag 3) all
 315 others were considered as good data (flag 2, i.e. 97%). This is better than the statistics we evaluated for the
 316 SNAPO-CO2-v1 dataset (90% flag 2 for MOOSE-GE in 2010-2019). A similar control was performed for each
 317 project.

319 3.4 Inter-comparisons

320

Inter-comparisons of measurements performed for different cruises or with different techniques help to evaluate the quality of the data and detect potential biases when merging the data in the same region obtained by different laboratories at different periods. This is especially important to interpret long-term trends of A_T and C_T as well as for pCO_2 and pH calculated with A_T C_T pairs. The synthesis of various cruises in the same region and periods also offers verification and secondary control of the data.

326

327 3.4.1 Comparisons in deep layers

328

Comparisons of data in the deep layers from different cruises are useful for secondary quality control as one expects low natural variability or anthropogenic signals from season to season and over a few years. Several cruises were conducted in the Mediterranean Sea in 2017-2023 (MOOSE-GE, ANTARES and DYFAMED). The mean values of C_T and A_T in the deep layers (> 1800m) for each cruise confirmed the coherence of the data (Table 4). The C_T and A_T concentrations are also in the range of the mean values evaluated for cruises conducted in 2014 in the Mediterranean Sea (results listed in the SNAPO-CO2-v1 synthesis, Metzl et al., 2024a). In the western tropical Pacific we also observed coherent properties for the TONGA and OUTPACE cruises (Wagener et al., 2018) for data selected at 1800-2300m layer corresponding to the C_T maximum layer in the Pacific Deep Water (PDW). On the other hand in the western tropical Atlantic near the Amazon River plume where the spatial variability of the properties is large at the surface (Ternon et al., 2000; Mu et al., 2021; Olivier et al., 2022) the comparison in the water column is less clear (Figure S4). Nevertheless for the AMAZOMIX and the TARA-Microbiome cruises, both conducted in September 2021, the results at close stations (around 5°N/50°W) suggest very similar concentrations at 1000m (Table 4). The comparisons in deep waters enabled to merge the different datasets for interpretations of the temporal trends and processes driving the CO₂ cycle in these regions (e. g. Ulles et al., 2023 and Wimart-Rousseau et al., 2023 for the Mediterranean Sea)

344

345 3.4.2 Comparing on board and on shore results

346

In surface waters where the variability is high inter-comparison is not relevant for secondary quality control. However, during the MINERVE cruises, discrete samples were occasionally performed along with sea surface underway measurements. Thus, we can compare A_T and C_T measured in the laboratory with those measured onboard as described by Laika et al. (2009) for the MINERVE cruises in 2005-2006. It should be noticed that the discrete samples were measured after a long trip (shipping boxes from Hobart, Tasmania to Paris, France) and thus generally analyzed at least 3 months after the cruises (cruises conducted in October to February, analyses performed in May-June). Given all the uncertainties associated to the sampling, samples storage and transport, analyses and CRMs, the mean differences between discrete and underway data are still reasonable (Std ranging between 4 and 12 $\mu\text{mol kg}^{-1}$, Table 5). For unknown reasons the mean difference was high for a cruise in 2008-2009 (Std $> 10 \mu\text{mol kg}^{-1}$, the “weather goal”, Newton et al., 2015). With this in mind, we believe the MINERVE data (both underway and discrete data) are useful to interpret the change of properties in this region at seasonal or decadal scales (Laika et al., 2009; Brandon et al., 2022).

359

360
 361 **Table 4:** Mean observations in the deep layers (> 1800m) of the Ligurian Sea (Western Mediterranean Sea for
 362 different cruises conducted in 2017-2023), of the Tropical Pacific (around 2000m for cruises in 2017 and 2019),
 363 and of the Tropical Atlantic (around 1000m for cruises in 2021). N- A_T and N- C_T are A_T and C_T normalized at
 364 salinity (S = 38 in the Ligurian Sea; S= 35 for the Pacific and the Atlantic Oceans). Nb = number of data (with
 flag 2). Standard deviations are in brackets.

Cruise	Period	Nb	Pot. Temp (°C)	Salinity	N- A_T ($\mu\text{mol kg}^{-1}$)	N- C_T ($\mu\text{mol kg}^{-1}$)
Ligurian Sea (> 1800m)						
All Cruises	2017-2023	227	12.923 (0.052)	38.484 (0.003)	2558.3 (10.5)	2300.0 (10.7)
DYFAMED	2017-2022	74	12.913 (0.006)	38.485 (0.002)	2555.1 (11.8)	2297.3 (12.4)

TARA-MICRO	2021	1	4.852	34.717	2312.9	2231.1

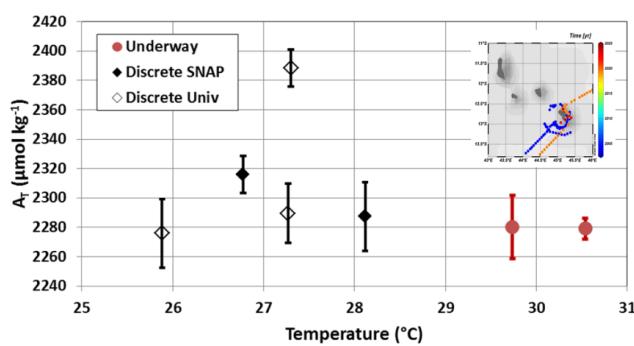

403 **Table 5:** Comparison of A_T and C_T analysed on-board and at SNAPO-CO2 facilities for the MINERVE project.
 404 The results are expressed as the standard deviations (Std) of the differences for each cruise. Nb = the number of
 405 co-located samples.

Period	Nb	Std A_T $\mu\text{mol kg}^{-1}$	Std C_T $\mu\text{mol kg}^{-1}$
2004-2005	109	12.85	4.99
2005-2006	45	4.20	6.77
2007-2008	17	10.15	10.62
2008-2009	26	15.80	12.02
2009-2010	22	4.04	5.78
2010-2011	33	9.36	6.83
2012-2013	29	5.43	9.73

422 **3.4.3 Comparison based on different techniques**

423

424 Another example of comparison is presented for samples obtained in the lagoon of Mayotte Island in
 425 the western Indian Ocean and measured using different techniques. In the frame of the CARBODISS project
 426 seawater was sampled in 2018-2023 at several coral reef sites within the north-eastern part of the lagoon and
 427 measured either at LOCEAN laboratory or at La Réunion University. To remove coral sand particles the water
 428 samples were immediately filtered through Whatman GF/F filters and poisoned with mercuric chloride,
 429 following Dickson et al. (2007). In 2021, 2022 and 2023, A_T was measured at La Réunion University using an
 430 automated potentiometric titration (905 Titrando Metrohm titrator with combined pH electrode 6.0253.00) and
 431 calculated from the second inflection point of the titration curve. The HCl concentration was checked each day
 432 of measurements using a CRM provided by A. Dickson, Scripps Institution of Oceanography. The A_T precision
 433 of $\pm 2 \mu\text{mol kg}^{-1}$ was based on triplicate was estimated $\pm 2 \mu\text{mol kg}^{-1}$ -analyses (Lagoutte et al., 2023). In the
 434 studied coral reef sites A_T concentrations ranged between 2250 and 2350 $\mu\text{mol kg}^{-1}$ but with occasional higher
 435 concentrations up to 2450-2500 $\mu\text{mol kg}^{-1}$. Such high A_T has been observed in other coral reefs ecosystems
 436 (Cyronak et al., 2013 at Cook Island; Palacio-Castro et al., 2023 at Middle Keys, Florida). The data obtained in
 437 the lagoon of Mayotte on different coral reefs could be compared with underway observations obtained offshore
 438 of Mayotte Island (OISO-11 cruises in 2004 and CLIM-EPARSES cruise in 2019, data available in the SNAPO-
 439 CO2-v1 dataset). In the open ocean the A_T concentrations ranged between 2250 and 2330 $\mu\text{mol kg}^{-1}$, close to the
 440 results obtained at Mayotte reefs except for samples in November 2021 that were all collected at Cratère station
 441 (12.84°S-45.39°E) (Figure 4). At this location there was a large diurnal variation in November 2021 with A_T
 442 increasing from 2322 to 2508 $\mu\text{mol kg}^{-1}$ (Figure S5). This is because in 2021 the samples were taken at low tide
 443 recording a volcanic signal at this site allowing recording for the first time the volcanic signal in this location
 444 (CO_2 resurgences). In 2018 and 2019 such high A_T were not measured (Figure S5) as samples were taken at high
 445 tides allowing a certain dilution of volcanic CO_2 emissions in the water column. Although the samples were
 446 measured with different techniques the range of A_T is coherent for both datasets (Figure 4). Therefore we added
 447 the A_T data measured at La Réunion University in 2021-2023 to complete the synthesis for this location (Mayotte
 448 Island).

462 **Figure 4:** Total alkalinity (A_T) versus temperature for samples measured around Mayotte and in the coral reef
 463 (insert map). Underway A_T was measured onboard in 2004 and 2019 (red circles) whereas discrete samples at
 464 different reef sites within the lagoon of Mayotte in 2018, 2019, 2021, 2022 and 2023 were measured at

465 LOCEAN (black diamonds) or at La Réunion University (open diamonds). The figure presents the data averaged
466 for each cruise in this region.

467

468 **3.4.4 Summary of quality control data**

469

470 The total number of data in the SNAPO-CO2-v2 dataset for the Global Ocean is gathered in Table 6
471 with corresponding flags for each property. Overall, the synthesis includes more than 91% of good data for both
472 A_T and C_T . About 6% are questionable and 3% are likely bad. Overall, we believe that all data (with flag 2) in
473 this synthesis have an accuracy better than 4 $\mu\text{mol kg}^{-1}$ for both A_T and C_T , the same as for quality-controlled
474 data in GLODAP (Lauvset et al., 2024). The uncertainty ranges between the “Climate goal” (2 $\mu\text{mol kg}^{-1}$) and
475 the “Weather Goal” (10 $\mu\text{mol kg}^{-1}$) for ocean acidification studies (Newton et al., 2015; Tilbrook et al., 2019).
476 This accuracy is also relevant to validate or constraint data-based methods that reconstruct A_T and C_T fields with
477 an error of around 10–15 $\mu\text{mol kg}^{-1}$ for both properties (Bittig et al., 2018; Broullón et al., 2019, 2020; Fourrier et
478 al., 2020; Gregor and Gruber, 2021; Chau et al., 2024a).

479

480

481 **Table 6:** Number of Temperature, Salinity, A_T and C_T data in the SNAPO-CO2-v2 synthesis identified for flags
482 2 (good), 3 (questionable), 4 (bad), 9 (no data). Last column is the percentage of flag 2 (Good).

483

484

Property	Flag 2	Flag 3	Flag 4	Flag 9	% flag 2
Temperature	68253	418	0	653	99.4
Salinity	68706	482	5	131	99.3
A_T	61249	3910	2077	2088	91.1
C_T	61869	3865	2057	1533	91.3

492

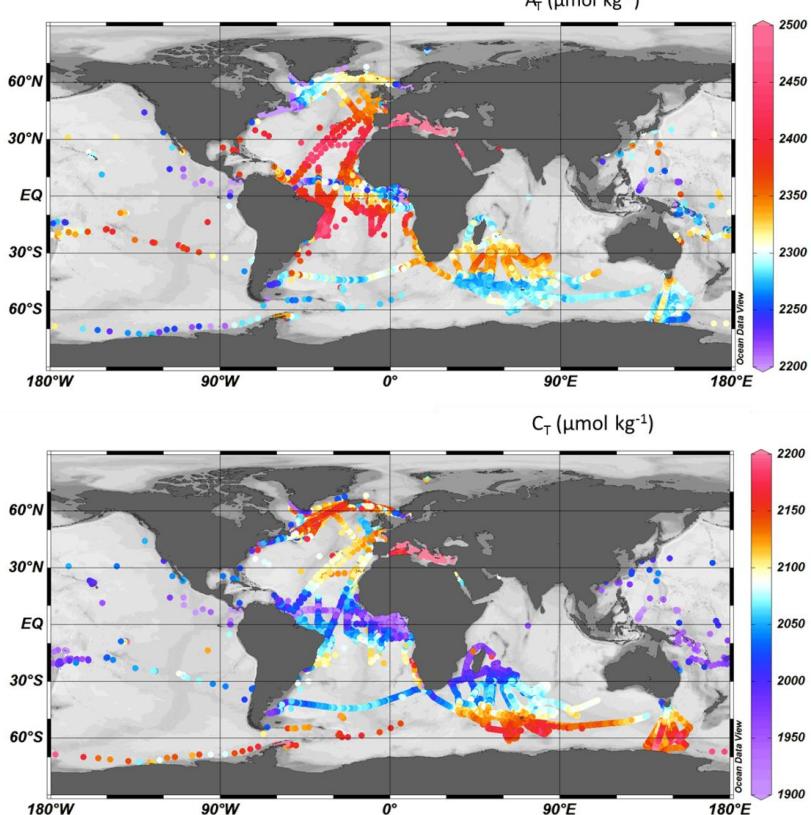

493

494 **4 Global A_T and C_T distribution based on the SNAPO-CO2-v2 dataset**

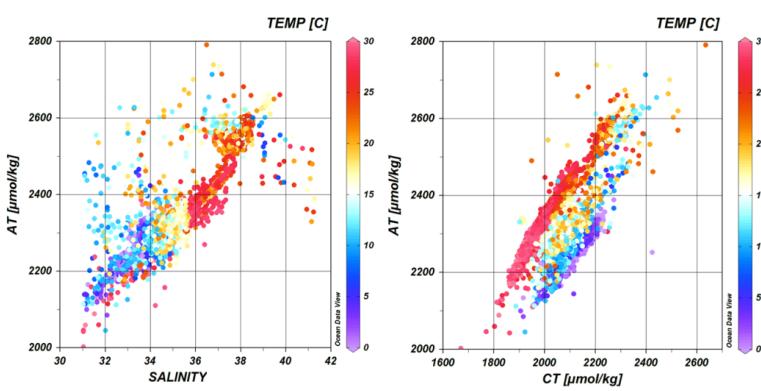

495

496 The surface distribution in the global ocean based on the SNAPO-CO2 dataset is presented in Figure 5
497 for A_T and C_T . The A_T /Salinity and A_T/C_T relationships are clearly identified and structured at regional scale
498 (Figure 6). In the open ocean, high A_T concentrations ($> 2400 \mu\text{mol kg}^{-1}$) are identified in the Atlantic subtropics
499 (bands 35°N–15°N and 25°S–3°S) (Jiang et al., 2014; Takahashi et al., 2014). The lowest A_T and C_T
500 concentrations ($< 600 \mu\text{mol kg}^{-1}$) are observed in the western tropical Atlantic in the Amazon River plume near
501 the mouth (Lefèvre et al., 2017b). For C_T the concentrations are high ($> 2150 \mu\text{mol kg}^{-1}$) in the Southern Ocean
502 south of the polar front, associated with the deep mixing in winter and the upwelling of deep water (Metzl et al.,
503 2006; Pardo et al., 2017). The highest C_T concentrations (up to 2180–2270 $\mu\text{mol kg}^{-1}$) are observed in the high
504 latitudes of the Southern Ocean near the Adélie coastal zone (MINERVE and ACE cruises), around the
505 Kerguelen plateau (OISO-31 cruise) and close to the Antarctic Peninsula (TARA-Microbiome cruise). In the
506 North Atlantic the new data from SURATLANT cruises in 2018–2023 confirm the high C_T concentrations ($>$
507 2150 $\mu\text{mol kg}^{-1}$) observed in the Sub-polar gyre since 2016 due in part to the accumulation of anthropogenic CO₂
508 (Leseurre et al., 2020). Low C_T concentration ($< 2000 \mu\text{mol kg}^{-1}$) are found in the tropics (10°N–30°S) with
509 lower values ($< 1950 \mu\text{mol kg}^{-1}$) in the equatorial Atlantic band 10°N–Eq (e.g. Koffi et al., 2010; Lefèvre et al.,

510 2021). In the Amazon shelf sector C_T can reach even lower concentration (< 1700 $\mu\text{mol kg}^{-1}$, AMAZOMIX
 511 cruise).

541 **Figure 5:** Distribution of A_T (top) and C_T (bottom) concentrations ($\mu\text{mol.kg}^{-1}$) in surface waters (0-10m) in the
 542 SNAPO-CO₂-v2 dataset. Only data with flag 2 are presented in these figures. Figures produced with ODV
 543 (Schlitzer, 2018).

562 **Figure 6:** Relationships between A_T and Salinity (left panel) and A_T versus C_T (right panel) for samples in
 563 surface waters (0-10m and Salinity > 31). Only data with flag 2 are presented (nb = 48749). The color scales

564 correspond to the temperature. The data not aligned correspond to coastal zones (e.g. COCORICO2 stations).
565 Figures produced with ODV (Schlitzer, 2018).

567 **5 Regional A_T and C_T distributions and trends based on the SNAPO-CO2 dataset**

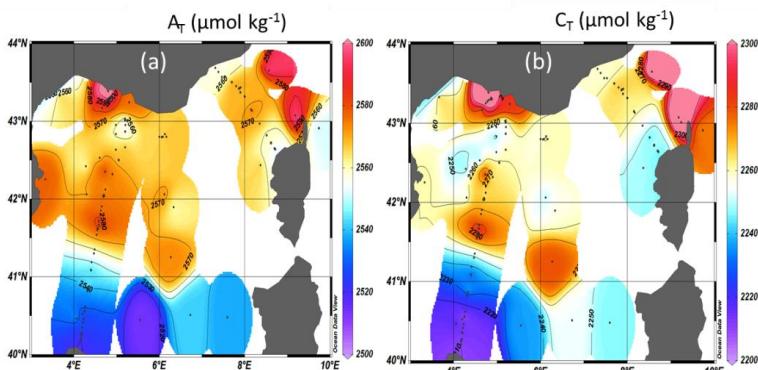

568
569 The regional distributions are described for the Mediterranean Sea and for selected regions in the open
570 ocean and coastal zones where the data are available for 10 years or more to explore the A_T and C_T trends. Given
571 the observed seasonal and inter-annual variability and that the time-series were not regular (e.g. at monthly
572 frequency), we cannot use recommended methods to estimate the trends (e.g. based on de-seasoned data, Sutton
573 et al., 2022). Here we have selected the locations and seasons where the C_T trends can be linearly fitted and
574 compared with no interpolation to fill gaps and discontinuous data (e.g., fewer samples during the COVID
575 period).

576 **5.1 The Mediterranean Sea**

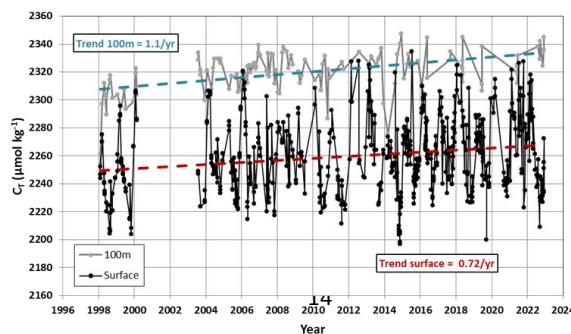

577 Compared to the open ocean, A_T concentrations are much higher in the Mediterranean Sea (Copin-
578 Montégut, 1993; Schneider et al., 2007; Álvarez et al., 2023) with values up to $2600 \mu\text{mol kg}^{-1}$. The A_T and C_T
579 data obtained in 2014-2023 show a clear contrast between the northern and southern regions of the Western
580 Mediterranean Sea with higher concentration in the Ligurian Sea and the Gulf of Lion (Figure 7). This contrast is
581 associated to the circulation and the frontal system in this region (e.g. Barral et al., 2021). New data in the coastal
582 zones in the Gulf of Lion (ACCESS, DICASE, CARBODELTA, COCORICO2, MESURHOBENT) also have
583 very high A_T and C_T concentrations ($A_T > 2600 \mu\text{mol kg}^{-1}$; $C_T > 2350 \mu\text{mol kg}^{-1}$). Very low A_T and C_T
584 concentrations ($A_T < 2500 \mu\text{mol kg}^{-1}$; $C_T < 2200 \mu\text{mol kg}^{-1}$) were also occasionally observed in the coastal zones
585 (COCORICO2 stations, Petton et al., 2024).

586 In summer 2022 the Mediterranean Sea experienced an exceptional warming (Figure S6) superposed to
587 the long-term warming in the ocean (Cheng et al., 2024). Such event would impact the internal ocean processes
588 such as thermodynamic, stratification and biological processes (Coppola et al., 2023) and the inter-annual
589 variability and trends of C_T , pH, $f\text{CO}_2$ and air-sea CO_2 fluxes (Yao et al., 2016; Wimart-Rousseau et al., 2023;
590 Chau et al., 2024b). As in 2003, the warming in summer 2022 was associated to the drought event that occurred
591 in Europe and over the Mediterranean Sea (Faranda et al., 2023). In July 2022, the maximum temperature of
592 28.42°C was observed at station SOMLIT-Point-B. In the Ligurian Sea the temperature trend was faster in recent
593 years, $+0.173 \pm 0.072^\circ\text{C}$ per decade over 1990-2010 and $+0.678 \pm 0.143^\circ\text{C}$ per decade over 2010-2023 (Figure
594 S6). With the new data added in the SNAPO-CO2-v2 synthesis (DYFAMED, MOOSE-ANTARES, and
595 MOOSE-GE) we evaluated a temperature trend of $+0.84 \pm 0.20^\circ\text{C}$ per decade over 1998-2022 indicating that
596 the discrete sampling captured the property changes at regional scale. Based on the data in the Ligurian Sea the
597 trends of C_T appeared faster in summer ($+1.53 \pm 0.46 \mu\text{mol kg}^{-1} \text{yr}^{-1}$) than in winter ($+0.94 \pm 0.64 \mu\text{mol kg}^{-1} \text{yr}^{-1}$,
598 Table 7). On the other hand, the trends of A_T were the same ($+0.72 \pm 0.36 \mu\text{mol kg}^{-1} \text{yr}^{-1}$ in winter and $+0.69 \pm$
599 $0.42 \mu\text{mol kg}^{-1} \text{yr}^{-1}$ in summer). The trend of C_T in surface in winter was close to the one derived at 100m (below
600 the Chl-a maximum), $C_T^{100\text{m}} = +1.10 \pm 0.17 \mu\text{mol kg}^{-1} \text{yr}^{-1}$ (Figure 8) whereas for A_T the trend was the same in
601 surface and at depth ($+0.76 \pm 0.12 \mu\text{mol kg}^{-1} \text{yr}^{-1}$). This suggests that the winter C_T data recorded the
602 anthropogenic CO_2 uptake of around $+1 \mu\text{mol kg}^{-1} \text{yr}^{-1}$, Figure S7). Note that, given the observed C_T trends, the
603

605 | spatial view presented in Figure 7b for 2014-2023 would be the same based on C_T concentrations normalized to
 606 | a reference year (not shown). As noted by Touratier and Goyet (2009) the C_T concentrations in the
 607 | Mediterranean Sea should increase in parallel with the level of atmospheric anthropogenic CO₂. For an
 608 | atmospheric CO₂ rate of +2.16 ppm yr⁻¹ over 1998-2023 (Lan et al., 2024) and at fixed sea surface temperature
 609 | (17.75°C), salinity (38.25) and A_T (2567 μmol kg⁻¹), the theoretical C_T increase would be +1.24 μmol kg⁻¹ yr⁻¹.
 610 | Interestingly, an anthropogenic flux of -0.3 ± 0.02 molC m⁻² yr⁻¹ in the Mediterranean Sea (Bourgeois et al.,
 611 | 2016) would correspond to an increase of C_T of 1.07 ± 0.07 μmol kg⁻¹ yr⁻¹ in the top 100 meters. This is again
 612 | close to what is observed in winter or at 100m (Table 7, Figure 8). On the other hand the faster C_T trend
 613 | observed in surface waters during summer might be associated with a decrease in biological production and/or
 614 | changes in circulation/mixing over time that deserve specific investigations such as analyzed for the oxygen
 615 | budget in this region (Ulses et al., 2021). It is worth noting that the C_T and A_T trends in coastal zones of the
 616 | Mediterranean Sea are opposite to those observed offshore: for example at station SOLEMIO (Bay of Marseille,
 617 | Wimart-Rousseau et al., 2020) the C_T and A_T concentrations decreased over 2016-2022 and thus opposed to the
 618 | anthropogenic CO₂ signal, indicating that processes such as riverine inputs, advection or biology control the
 619 | carbonate system decadal variability at local scale. This calls for developing dedicated complex biogeochemical
 620 | models to resolve these processes (Barré et al., 2023, 2024), especially when extreme events occurred, such as
 621 | the very hot summer in 2024 with SST up to 30°C in the Mediterranean Sea (Platforms Buoy/Mooring AZUR,
 622 | EOL and La Revellata, data available at <https://dataselection.coriolis.eu.org/>). The data obtained in the
 623 | Mediterranean Sea are important not only to validate biogeochemical models but also to reconstruct the
 624 | carbonate system from A_T and pCO_2 data (Chau et al., 2024a) as the global A_T /SSS relationships (e.g. Carter et
 625 | al., 2018) are not suitable for this region.

636 | **Figure 7:** Distribution of A_T (a) and C_T (b) in $\mu\text{mol kg}^{-1}$ in surface waters of the Mediterranean Sea (0-10m) from
 638 | observations over 2014-2023. Figures produced with ODV (Schlitzer, 2018).

656 Ligurian Sea. The trends over 1998-2022 is surface (red) and at 100m (blue) are indicated by dashed lines.
657

658 **5.2 The North Atlantic**

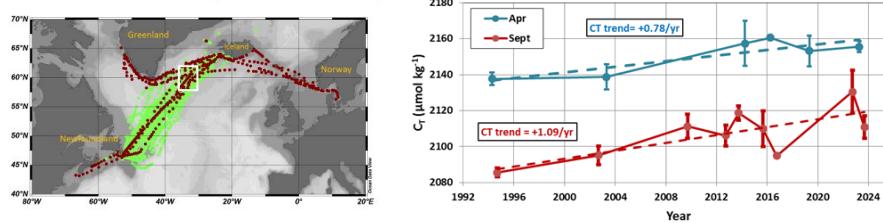

660 The North Atlantic Ocean is an important CO₂ sink (Takahashi et al. 2009) due to biological activity
661 during summer, heat loss and deep convection during winter. As a result this region contains high concentrations
662 of anthropogenic CO₂ (C_{ant}) in the water column (Khatiwala et al., 2013). Decadal variations of the C_{ant}
663 inventories were recently identified at basin scale probably linked to the change of the overturning circulation
664 (Gruber et al., 2019; Müller et al., 2023; Pérez et al., 2024). This region experienced climate modes such as the
665 North Atlantic Oscillation (NAO) and the Atlantic Multidecadal Variability (AMV) that imprint variability in
666 air-sea CO₂ fluxes at inter-annual to multidecadal scales (e.g. Thomas et al., 2008; Jing et al., 2019;
667 Landschützer et al., 2019) but not always clearly revealed at regional scale (Metzl et al., 2010; Schuster et al.,
668 2013; Pérez et al., 2024). In addition it has been recently shown that extreme events such as the marine heat
669 wave in summer 2023 leaded to a reduce CO₂ uptake in this region (Chau et al., 2024b). Although the annual
670 CO₂ fluxes deduced from Global Ocean Biogeochemical Models (GOBM) seem coherent with the data-products
671 at basin scale (resp. -0.30 ± 0.07 and -0.24 ± 0.03 PgC/yr for the [North Atlantic subpolar seasonally stratified](#),
672 NA-SPSS biome) the pCO_2 cycle seasonality is not well simulated (Pérez et al., 2024). Therefore to correct the
673 GOBMs outputs, comparisons with the observed C_T and A_T cycles are also needed.

674 In this context regular sampling in the North Atlantic (OVIDE cruises, Mercier et al., 2015, 2024;
675 SURATLANT transects, Reverdin et al., 2018) and time-series stations in the Irminger and Iceland Seas
676 (Ólafsson, et al., 2010; Lange et al., 2024; Yoder et al., 2024) are important to explore the variability of the
677 biogeochemical properties from seasonal (Figure S8) to decadal scales (Figure 9). The SURATLANT data added
678 in the SNAPO-CO2-v2 dataset over 2017-2023 offer new observations in the North Atlantic Subpolar Gyre
679 (NASPG in the NA-SPSS biome) and new transects from Norway to Iceland and reaching the coast of Greenland
680 (Figure 9). In 2010 the winter NAO was negative, moved to a positive state in 2012-2020 and was again very
681 low in 2021. The new SURATLANT data after 2017 confirm the cooling and the freshening in the NASPG since
682 2009 (Holliday et al., 2020; Leseurre et al., 2020; Siddiqui et al., 2024) whereas the most recent data in 2022 and
683 2023 suggest a reverse trend (increase of salinity and temperature, not shown). After 2016, large C_T anomalies in
684 the NASPG were observed. For examples, in April 2019 and 2022, the C_T concentrations were low compared to
685 2016 (Figure 9) and opposed to the expected anthropogenic CO₂ uptake. In September 2023 the C_T
686 concentrations were much lower than in 2022 (Figure 9) probably linked to biological productivity when the
687 NAO index was negative (Fröb et al., 2019) as observed in summer 2023 (NAO < -2 in July 2023). Despite these
688 variability the C_T trends are relatively well evaluated (Table 7). As in the Mediterranean Sea the C_T trends in the
689 NASPG appeared different depending on the season (Figure 9). The C_T increase was faster in September than in
690 April (resp. $+1.09 \pm 0.37 \mu\text{mol kg}^{-1} \text{yr}^{-1}$ and $+0.78 \pm 0.23 \mu\text{mol kg}^{-1} \text{yr}^{-1}$). This is either close to or lower than the
691 theoretical C_T increase due to the rising of atmospheric CO₂ ($+0.91 \mu\text{mol kg}^{-1} \text{yr}^{-1}$) and in the range of recent

692 results evaluated for the Sub-polar Mode Waters in the Irminger Sea (C_{ant} trend = $0.95 \pm 0.17 \mu\text{mol kg}^{-1} \text{ yr}^{-1}$ for
 693 the period 2009–2019, Curbelo-Hernández et al., 2024).

694

695

704 **Figure 9:** Left: Data in SNAPO-CO₂-v1 (green) and new data in v2 (brown) from the SURATLANT cruises in
 705 1993–2023 in the North Atlantic. Figure produced with ODV (Schlitzer, 2018). The white box identified the
 706 region of selected data around 60°N for the trend analysis. Right: Time-series of average C_T concentrations in
 707 April (blue) and September (red) in this region. The trends for each season are indicated (see also Table 7).
 708

709 5.3 The Tropical Atlantic

710

711 In the Tropical Atlantic, previous studies highlighted the large variability of biogeochemistry and the
 712 difficulty in detecting long-term trends of C_T (e.g. Lefèvre et al., 2021). This is related to the variability of
 713 circulation, equatorial upwelling, biological processes (some linked to Saharan dust) and inputs from large rivers
 714 (Congo, Amazon and Orinoco). The new data added in version SNAPO-CO₂-v2 (Figure S9) show the
 715 contrasting zonal C_T distribution in this region with lower concentrations in low salinity regions of the North
 716 Equatorial Counter Current and Guinea Current (Figure 5; Oudot et al., 1995; Takahashi et al., 2014; Broullón et
 717 al., 2020; Bonou et al., 2022). For exploring the temporal changes we selected the data in the western region
 718 available for at least 10 years and separated the northern and southern sectors. In both regions the C_T trend is
 719 close to $+3 \mu\text{mol kg}^{-1} \text{ yr}^{-1}$ (Table 7, Figure S9) much higher than the expected anthropogenic signal. In this
 720 region where coastal water masses mixes with oceanic waters, the inter-annual variability of C_T is large and the
 721 changes driven by competitive processes (circulation, biological processes). More observations and dedicated
 722 models are needed to separate the anthropogenic and natural variability in this region (Pérez et al., 2024).

723

724 5.4 The Southern Ocean

725

726 In the Southern Ocean there are a few regular multi-annual observations of the carbonate system. Time
 727 series of more than 10 years were obtained in the Drake Passage (Munro et al., 2015) and in the Southern Indian
 728 Ocean (Leseurre et al., 2022; Metzl et al., 2024b). Observations were also obtained for more than 20 years
 729 southeast of New Zealand at the Munida Time Series (MTS) in the subtropical and sub-Antarctic frontal zones
 730 (Currie et al., 2011; Vance et al., 2024). To complement these datasets we have added the data collected in the
 731 South-Eastern Indian Ocean between Tasmania and Antarctica in the frame of the MINERVE cruises (Figure 10;
 732 Brandon et al., 2022). These cruises were conducted from October to March offering each year a view of the
 733 seasonal changes between late winter and summer from the sub-Antarctic zone to the coastal zone near
 734 Antarctica (Adélie land). In all sectors (here from 45°S to 67°S) the C_T concentrations were higher in October
 735 when the mixed-layer depth (MLD) was deep and were lower during the productive summer season (e.g. Laika

et al., 2009; Shadwick et al., 2015). An example is presented at 60°S/151°E from the data obtained along a reoccupied track in 2011-2012 (Figure S10). At this location south of the Polar Front in the POOZ/HNLC area ([Permanent Open Ocean Zone/ High Nutrient Low Chlorophyll](#)), the C_T concentrations were $+25 \mu\text{mol kg}^{-1}$ higher in October compared to February. The same seasonal amplitude was observed in the western Indian sector of the POOZ (Metzl et al., 2006, 2024b) suggesting that the C_T seasonality is relatively homogeneous in this region corresponding to the Indian SO-SPSS biome (Fay and McKinley, 2014). The difference in the climatological C_T between October and January is on average $+28.3 \pm 9.8 \mu\text{mol kg}^{-1}$ in the Indian Ocean POOZ (Takahashi et al., 2014). Given this seasonality and potential change in the seasonal amplitude over time (Gallego et al., 2018; Landschützer et al., 2018; Shadwick et al., 2023) the property trends have to be evaluated for October and January-February separately, here over 2002-2012 in the POOZ (Figure 10, Table 7). In both seasons, the average C_T concentrations reached a minimum in 2008 and increased faster in 2008-2012 (up to $+4.8 \mu\text{mol kg}^{-1} \text{ yr}^{-1}$). Interestingly, such acceleration of the trend after 2009 was observed for $p\text{CO}_2$ at the MTS station (Vance et al., 2024). We note that the C_T trend over 2002-2012 was slightly faster in October (Figure 10) probably linked to deeper MLD as suggested from the cooling and the salinity increase observed during this season (not shown).

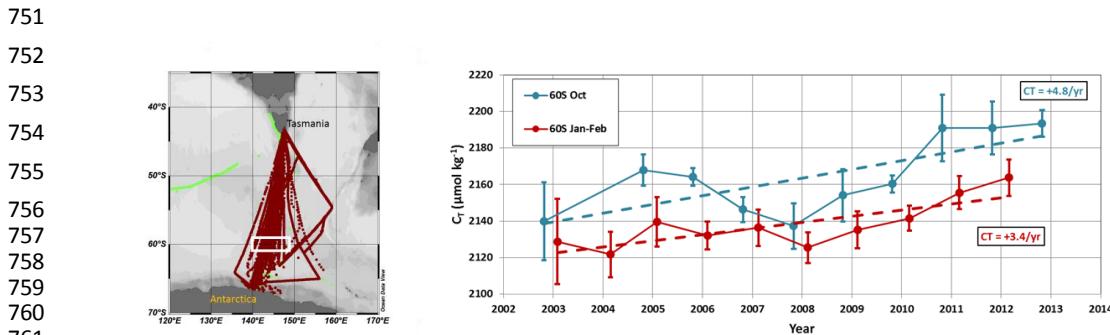

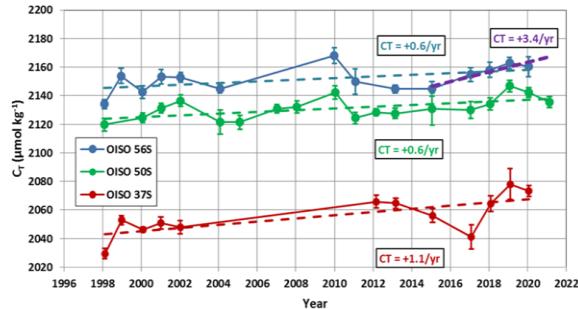

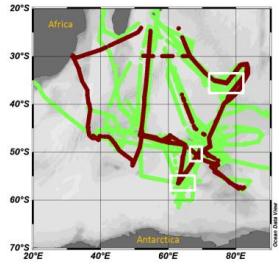

Figure 10: Left: Data in SNAPO-CO2-v1 dataset (green) and new data in version v2 (brown) in the South eastern Indian Ocean. Figure produced with ODV (Schlitzer, 2018). The white box identified the region of selected data around 60°S for the trend analysis. Right: Time-series of average C_T concentrations in January-February (red) and October (blue) around 60°S (white box in the map). The trends for each season are indicated (see also Table 7).

In the western Indian sector, the new data in the SNAPO-CO2-v2 dataset from the OISO cruises at high latitudes also recorded a rapid C_T trend over 5-8 years periods (e.g., $+3.4 \mu\text{mol kg}^{-1} \text{ yr}^{-1}$ in 2015-2020 at 56°S, Figure 11, Table 7). Although the inter-annual variability of C_T , between 10 and 20 $\mu\text{mol kg}^{-1}$, is often recognized (Figure 11), the evaluation of the trends over more than 20 years indicated faster trend in the subtropical Indian Ocean ($+1.1 \mu\text{mol kg}^{-1} \text{ yr}^{-1}$) compared to higher latitudes (Indian POOZ, $+0.6 \mu\text{mol kg}^{-1} \text{ yr}^{-1}$); they are close to the expected anthropogenic signal in these regions ($+1.1 \mu\text{mol kg}^{-1} \text{ yr}^{-1}$ in the subtropics and $+0.8 \mu\text{mol kg}^{-1} \text{ yr}^{-1}$ at higher latitudes).

5.5 The Coastal Zones

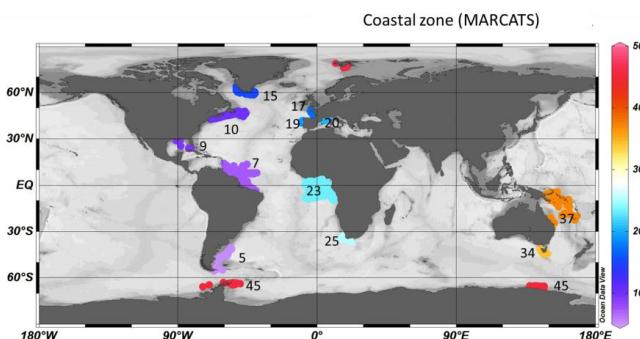

Coastal waters experience enhanced ocean acidification due to increasing CO₂ uptake, accumulation of anthropogenic CO₂ (Bourgeois et al 2016; Laruelle et al, 2018; Roobaert et al, 2024a; Li et al, 2024) and from local anthropogenic inputs through rivers or from air pollution (e.g. Sarma et al, 2015; Sridvi and Sarma, 2021; Wimart-Rousseau et al, 2020). The changes of the CO₂ uptake in coastal zones are also linked to biological processes (Mathis et al, 2024) or to circulation and local upwelling (Roobaert et al, 2024b), all controlling large variability of A_T and C_T in space and time leading to uncertainties for detecting long-term changes of pCO₂ and air-sea CO₂ fluxes in heterogeneous coastal waters (Dai et al 2022; Resplandy et al, 2024). At seasonal scale, large differences between observations and models were also identified leading to differences in the coastal ocean CO₂ sink up to 60% (Resplandy et al, 2024). It is thus important to document the seasonal cycles of A_T and C_T to compare and correct models and thus to better predict future changes of biogeochemical properties in coastal waters and their impact on marine ecosystems. A better understanding of the processes and their retroaction in the coastal regions is also required regarding Marine Carbone Dioxide Removal (MCDR) experiments and for their evaluation (e.g. Ho et al, 2023).

In the SNAPO-CO₂-v2 dataset new data have been added in the coastal zones at stations SOMLIT-Brest, SOMLIT-Roscoff and SOMLIT-Point-B. They extend the period to 2022 or 2023 for temporal analysis. New data in the French coastal zones have been also included from the COCORICO2 project documented in detail by Petton et al (2024). The observations in coastal zones could be identified in the MARCATS regions (Margins and CATchment Segmentation, Laruelle et al, 2013) (Figure 12) where little information is available for quantifying the ocean CO₂ sink at the decadal scale and for evaluation of the anthropogenic CO₂ uptake (Regnier et al, 2013; Dai et al, 2022; Li et al, 2024). To explore the change of the observed properties in the coastal zones and have a flavor of the long-term C_T trends we selected the time series with at least 10 years of data (Table 8, Figure 13). Except at high latitudes (Greenland and Antarctic coastal zones), we observed a warming in coastal zones (not shown). Changes in salinity are also identified (increase or decrease) and results

851 of the trends are presented for salinity-normalized C_T at 34, 35 or 38 depending on the region. Although the
852 inter-annual variability is large in coastal waters, sometimes linked to extreme events (e.g. river discharges), we
853 observed an increase in N- C_T at most of the 8 selected locations. The exceptions are the coastal zones in the Gulf
854 of Lion near the Rhone River and near Tasmania in October.

855 In the Gulf of Lion, the new data in the coastal zone confirmed the first view at the SOLEMIO station
856 over 2016-2018 (Bay of Marseille, Wimart-Rousseau et al, 2020). In this region the lowest C_T was observed in
857 summer 2022 (average C_T of $2238.6 \pm 21.0 \mu\text{mol kg}^{-1}$), much lower than in 2015 ($2290.8 \pm 44.7 \mu\text{mol kg}^{-1}$). Over
858 the continental shelf south of Tasmania (MARCATS #34), the trend in N- C_T was positive in summer but not
859 significant in October. In October this was associated with an increase in Salinity and in A_T probably linked to
860 advective processes via the reversal and variability of the Zeehan or the East Australian currents. From our data a
861 warming of $+0.06^\circ\text{C yr}^{-1}$ was identified for both seasons over 2002-2012 as previously observed south of
862 Tasmania over 1991-2003 impacting the $p\text{CO}_2$ trend and air-sea CO_2 fluxes in this region (Borges et al, 2008).
863 The difference in the N- C_T trends in austral summer and spring calls for new ~~detail~~detailed studies with extended
864 data in this region. At high latitude in the Adélie Land (Antarctic coast MARCATS #45), the variability of N- C_T
865 was large (range from 2150 to 2200 $\mu\text{mol kg}^{-1}$, Figure 13) and the trend over 10 years in summer was not
866 significant (Table 8). As opposed to the open zone at 60°S (Figure 10) the C_T concentrations in the coastal zone
867 near Antarctica were not increasing, probably linked to competitive processes between anthropogenic uptake,
868 changes in primary production, mixing or ice melting (Shadwick et al, 2013, 2014). More data are needed to
869 better evaluate the changes of the carbonate system in Antarctic coastal zones where bottom waters are formed
870 and transport anthropogenic CO_2 at lower latitudes (Zhang et al, 2023).

871 For the coastal time series SOMLIT where annual trends could be estimated (sampling at monthly
872 resolution), the N- C_T increase ($+2.1$ to $3.4 \mu\text{mol kg}^{-1} \text{yr}^{-1}$) is close or higher than the anthropogenic signal leading
873 to a decrease in pH ranging between -0.05 to $-0.06 \text{ TS decade}^{-1}$. The new data added in the SNAPO-CO₂-v2
874 dataset (2016-2023) confirm the progressive increase in C_T and the acidification in the western Mediterranean
875 Sea and in the North-East Atlantic coastal zones (Kapsenberg et al, 2017; Gac et al, 2021).

| **Figure 12:** Location of A_T and C_T data available in the coastal zones in the SNAPO-CO₂-v2 dataset. Numbers

936 **6 Summary and suggestions**

937
938 This work extends in time and in new oceanic regions the A_T and C_T data presented in the first SNAPO-
939 CO2 synthesis (Metzl et al, 2024a). It includes now more than 67 000 surface and water column observations in
940 all oceanic basins, in the Mediterranean Sea, in the coastal zones, near coral reefs, and in rivers. The data
941 synthesized in version v2 are based on measurements of A_T and C_T performed between 1993 and 2023 with an
942 accuracy of $\pm 4 \mu\text{mol kg}^{-1}$. Based on a secondary quality control, 91% of the A_T and C_T data are considered as
943 good (WOCE Flag 2) and 6% probably good (Flag 3). For the open ocean this synthesis complements the
944 SOCAT, GLODAP and SPOTS data products (Bakker et al., 2016; Lauvset et al., 2024; Lange et al, 2024). For
945 the coastal sites this also complements the synthesis of coastal time-series in the Iberian Peninsula (Padin et al,
946 2020), in the Canadian Atlantic continental shelf (Gibb et al, 2023) and around North America (Fassbender et al.,
947 2018; Jiang et al., 2021; Jiang et al 2024, in prep). The SNAPO-CO2 dataset enables to investigate the seasonal
948 cycles, the inter-annual variability and the decadal trends of A_T and C_T in various oceanic provinces. The same
949 temporal analyses could be investigated for other carbonate system properties such as $f\text{CO}_2$ or pH calculated
950 from A_T and C_T for air-sea CO_2 flux estimates or ocean acidification studies (Figure 14).

967 **Figure 14:** An example of observed ocean acidification derived from the SNAPO-CO2-v2 dataset: pH (TS)
968 calculated with A_T and C_T data are presented as a function of temperature ($^{\circ}\text{C}$) for years 1998-2002 (blue
969 symbols) and 2020-2023 (red symbols) and for salinity > 33 (Nb data selected with flag 2 = 11994). In recent
970 years the pH was lower. Figure produced with ODV (Schlitzer, 2018).

971
972 In almost all regions the new data in 2021-2023 indicated that the C_T concentrations were higher in
973 recent years. In regions where data are available for more than 2 decades, the time-series show an increase of sea
974 surface C_T (North Atlantic, Southern Indian Ocean and Ligurian Sea) with a rate close to or higher than the
975 changes expected from anthropogenic CO_2 uptake. It is also recognized that at seasonal scale the C_T trends could
976 be different. However, with the data in hand, the long-term trend of C_T cannot be quantified with confidence to
977 compare with the anthropogenic carbon uptake in some regions. This is the case in the eastern tropical Atlantic
978 subject to high inter-annual variability (Lefèvre et al., 2021, 2024) although new data have been added over
979 2005-2022 in this region (Table 1, Figure S9). When data are available for less than a decade the increase in C_T
980 was observed but the trend was uncertain due to large inter-annual variability (e.g. Adélie Land). An exception
981 was identified in the coastal zone in the Gulf of Lion (Mediterranean Sea) where summer data since 2010 present
982

983 a decrease in C_T most pronounced since 2015 (C_T trend = $-5.2 \pm 1.5 \text{ } \mu\text{mol kg}^{-1} \text{ yr}^{-1}$). Such C_T decrease over 10
984 years was also observed at the Hawaii Ocean Time series, HOT over 2010-2020 (Dore et al, 2009,
985 <https://hahana.soest.hawaii.edu/hot/hotco2/hotco2.html>, last access: 27 August 2024).

986 Although the A_T concentrations present significant inter-annual variability such as in the NASPG, in the
987 Topical Atlantic or the Adélie land and coastal zones, A_T appears relatively constant over time except at these
988 locations. In the open ocean, we observed an increase of A_T in the Southern Ocean south of the Polar Front
989 around 60°S in 2003-2012 not directly linked to salinity. In the coastal zones a decrease of A_T was pronounced
990 south of Greenland. In the coast in the Gulf of Lion, as observed for C_T , A_T decreased (A_T trend = $-2.8 \pm 1.2 \text{ } \mu\text{mol}$
991 $\text{kg}^{-1} \text{ yr}^{-1}$). This is opposed to the changes observed in the Ligurian Sea at station SOMLIT-Point-B, where C_T and
992 A_T increased over 2007-2015 (Kapsenberg et al, 2017) highlighting the contrasting C_T and A_T trends in the
993 Mediterranean coastal zones where ocean acidification is detected (here over 2008-2022, pH trend of -0.048
994 $\pm 0.003 \text{ decade}^{-1}$). With the continuous warming, reduced stratification and the rapid pH change observed in the
995 Mediterranean Sea, how the marine ecosystems will respond in the future should be addressed (e.g. Howes et al,
996 2015; Maugendre et al 2015; Lacoue-Labarthe et al, 2016). The SNAPO-CO2-v2 dataset could also be used to
997 explore and analyze the changes of the carbonate system occurring during extreme events such as marine heat
998 waves, rapid freshening, deep convection or high phytoplankton bloom events.

999 This dataset ~~would~~could also serve for validating autonomous platforms capable of measuring pH and
1000 $f\text{CO}_2$ properties (Sarmiento et al, 2023) and, along with other synthesis products (Jiang et al, 2024 in prep.),
1001 provides an additional reference dataset for the development and validation of regional biogeochemical models
1002 for simulating air-sea CO_2 fluxes. Thanks to the RECCAP2 stories, it has been recognized that Ocean
1003 Biogeochemical Models present biases in the seasonal cycle of C_T and A_T due to inadequate representation of
1004 biogeochemical cycles (e.g. Hauck et al, 2023; Rodgers et al, 2023; Sarma et al, 2023; Pérez et al, 2024;
1005 Resplandy et al, 2024). The SNAPO-CO2-v2 dataset could be used to guide analyses for regional or global
1006 biogeochemical models for A_T and C_T comparison and validation from seasonal to decadal scales. Our dataset is
1007 also essential for training and validating neural networks capable of predicting variables in the carbonate system
1008 (e.g. Fourier et al, 2020; Chau et al, 2024a; Gregor et al, 2024), thereby enhancing observations of marine CO_2 at
1009 different spatial and temporal scales. Furthermore, we encourage the use of this dataset (or part of it), at sea or
1010 prior going to sea for cruise planning. Indeed, using the approach of Davis and Goyet (2021) which takes into
1011 account the multiple constraints (ship-time, number of samples, etc.), it is possible to determine the most
1012 appropriate sampling strategy (Guglielmi et al., 2022, 2023), to reach the specific scientific objectives of each
1013 cruise.

1014 The data presented here are available online on the Seanoe servor (<https://doi.org/10.17882/102337>) in a
1015 file identifying version v1 and v2. The sources of the original datasets (doi) with the associated references are
1016 listed in the Supplementary Material (Tables S3, S4). As for version v1 we invite the users to comment on any
1017 anomaly that would have not been detected or to suggest potential misqualification of data in the present product
1018 (e.g. data probably good although assigned with flag 3, probably wrong). As for SOCAT or GLODAP, we
1019 expect to update the SNAPO-CO2 dataset once new observations are obtained and controlled.

1020
1021 **7 Data availability**

1022 Data presented in this study are available at Seanoe (Metzl et al, 2024d, <https://www.seanoe.org>,
1023 <https://doi.org/10.17882/102337>. See also <https://doi.org/10.17882/95414> for version V1. The dataset is also
1024 available at <https://explore.webodv.awi.de/ocean/carbon/snapo-co2/>

1025

1026 *Author contributions.* NM prepared the data synthesis, the figures and wrote the draft of the manuscript with
1027 contributions from all authors. JF measured the discrete samples since 2014, with the help from CM and CLM,
1028 and prepared the individual reports for each project. NM and JF pre-qualified the discrete A_T/C_T data. CLM and
1029 NM are co-Is of the ongoing OISO project and qualified the underway A_T/C_T data from OISO cruises. FT and
1030 CG were PIs of the MINERVE cruises. All authors have contributed either to organizing cruises, sample
1031 collection and/or data qualification, and reviewed the manuscript.

1032

1033 *Competing interest.* The authors have the following competing interests: At least one of the (co-)authors is a
1034 member of the editorial board of Earth System Science Data

1035

1036 *Acknowledgments.* Most of the A_T and C_T data presented in this study were measured at the SNAPO-CO2 facility
1037 (Service National d'Analyse des Paramètres Océaniques du CO2) housed by the LOCEAN laboratory and part of
1038 the OSU ECCE Terra at Sorbonne University and INSU/CNRS analytical services. Support by INSU/CNRS, by
1039 OSU ECCE Terra and by LOCEAN, is gratefully acknowledged as well as support by different French “Services
1040 nationaux d’Observations”, such as OISO/CARAUS, SOMLIT, PIRATA, SSS and MOOSE. We thank the
1041 research infrastructure ICOS (Integrated Carbon Observation System) France for funding a large part of the
1042 analyses. We thank the IRD (Institut de Recherche pour le Développement) and the French-Brazilian IRD-
1043 FAPEMA program for funding observations in the tropical Atlantic. We thank the French oceanographic fleet
1044 (“Flotte océanographique française”) for financial and logistic support for most cruises listed in this synthesis
1045 and for the OISO program (<https://campagnes.flotteoceanographique.fr/series/228/>). We acknowledge the
1046 MOOSE program (Mediterranean Ocean Observing System for the Environment,
1047 <https://campagnes.flotteoceanographique.fr/series/235/fr/>) coordinated by CNRS-INSU and the Research
1048 Infrastructure ILICO (CNRS-IFREMER). The CocoriCO2 project was founded by European Maritime and
1049 Fisheries Fund (grant no. 344, 2020–2023) and benefited from a subsidy from the Adour-Garonne water agency.
1050 We thank the following programs coordinated by A. Tribollet which have contributed to the acquisition of the
1051 data in Mayotte: CARBODISS funded by CNRS-INSU in 2018-2019, Future Maore reefs funded by Next
1052 Generation UE-France Relance in 2021-2023, and OA-ME funded by a Belmont Forum International (ANR) in
1053 2020-2026. We thank the program Mermex-Mistral CNRS for supporting AMOR-BFlux, CARBORHONE,
1054 DICASE and MESURHOBENT cruises and the program EC2CO-INSU for supporting MISSRHODIA2 cruise.
1055 The ACCESS project was supported by CNRS MISTRALS and the DELTARHONE-1 by EC2CO-INSU. The
1056 ACIDHYPO project was founded by CNRS International Emerging Actions; we thank Captain and crew of the
1057 R/V Savannah from the Skidaway Institute of Oceanography (University of Georgia) for their support and
1058 technical assistance during the operations at sea. The AMAZOMIX project was funded by French
1059 Oceanographic Fleet, INSU (LEFE), IRD (LMI TAPICOA), CNES (TOSCA MIAMAZ project) and by the
1060 French-Brazilian international program GUYAMAZON. The OISO program was supported by the French
1061 institutes INSU (Institut National des Sciences de l’Univers) and IPEV (Institut Polaire Paul-Emile Victor), OSU

1062 Ecce-Terra (at Sorbonne Université), and the French program SOERE/Great-Gases. We also thank the Research
1063 Infrastructure ILICO (<https://www.ir-ilico.fr>). We warmly thank Alain Poisson who initiated the MINERVE
1064 program and performed many of the measurements onboard R/V Astrolabe from 2002 through 2018. We thank
1065 all colleagues and students who participated to the cruises and have carefully collected the precious seawater
1066 samples. We thank Frédéric Merceur (IFREMER) for preparing the page and data availability on Seanoe and
1067 Reiner Schlitzer (AWI) for including the SNAPO-CO₂ dataset in the ODV portal. We thank the associated editor
1068 Sebastiaan van de Velde to manage this manuscript, and Kim Currie and Toste Tanhua for their suggestions that
1069 helped to improve this article.
