41 **Abstract**

42 The ForestScan project was conceived to evaluate new technologies for characterising forest structure and biomass at Forest
43 Biomass Reference Measurement Sites (FBRMS). It is closely aligned with other international initiatives, particularly the
44 Committee on Earth Observation Satellites (CEOS) Working Group on Calibration & Validation (WGCV) aboveground
45 biomass (AGB) cal/val protocols, and is part of GEO-TREES, an international consortium dedicated to establishing a global
46 network of Forest Biomass Reference Measurement Sites (FBRMS) to support EO and encourage investment in relevant field-
47 based observations and science. ForestScan is the first demonstration of what can be achieved more broadly under GEO-
48 TREES, which would significantly expand and enhance the use of EO-derived AGB estimates.

49

50 We present data from the ForestScan project, a unique multiscale dataset of tropical forest three-dimensional (3D) structural
51 measurements, including terrestrial laser scanning (TLS), unpiloted aerial vehicle laser scanning (UAV-LS), airborne laser
52 scanning (ALS), and in-situ tree census and ancillary data. These data are critical for the calibration and validation of EO
53 estimates of forest biomass, as well as providing broader insights into tropical forest structure.

54

55 Data are presented for three FBRMS: FBRMS-01: Paracou, French Guiana; FBRMS-02: Lopé, Gabon; and FBRMS-03:
56 Kabilis-Sepilok, Malaysia. Field data for each site include new 3D LiDAR measurements combined with plot tree census and
57 ancillary data, at a multi-hectare scale. Not all data types were collected at all sites, reflecting the practical challenges of field
58 data collection. We also provide detailed data collection protocols and recommendations for TLS, UAV-LS, ALS and plot
59 census measurements for each site, along with requirements for ancillary data to enable integration with ALS data (where
60 possible) and upscaling to EO estimates. We outline the requirements and challenges for field data collection for each data
61 type and discuss the practical considerations for establishing new FBRMS or upgrading existing sites to FBRMS standard,
62 including insights into the associated costs and benefits.

63 **1. Introduction**

64 Our capability to estimate forest structure and AGB has rapidly advanced, leveraging new remote sensing observations from
65 ground, air, and space. This progress underscores the importance of quantifying and understanding terrestrial carbon sources
66 and sinks, the response of global forests to climate change, and conservation and restoration efforts at local to global scales.
67 These new measurements broadly fall into the following categories:

68

69 1) TLS provides highly detailed (centimetre-scale) 3D structural measurements across hectare scales, enabling non-
70 destructive AGB estimates that are independent of, yet complementary to, empirical allometric model estimates (e.g.
71 Calders et al., 2022; Demol et al., 2024).

72

73 2) UAV-LS has evolved from highly specialised and expensive surveying platforms to more operational, low-cost
74 systems that offer coverage of several to thousands of hectares, with hundreds to thousands of points per square metre
75 from above. These data can be used to estimate forest canopy height, basal area, tree crown size and shape, vertical
76 structure, and AGB via allometric model functions of tree properties, including height, diameter at breast height
77 (DBH), and crown shape (Brede et al., 2022a; Kellner et al., 2019) However, as UAV-LS systems proliferate, the
78 need for intercalibration between sensors increases, due to differences in scanner and laser properties such as power,
79 wavelength, divergence, and scan rate, which result in notable variations in penetration and object detection rates
80 (Vincent et al., 2023).

81
82 3) Airborne laser scanning (ALS) has been a well-established tool in forestry and forest ecology since the 1990s. ALS
83 is routinely used to estimate forest height, structure, and AGB at stand level via empirical models and at regional to
84 national scales via allometric models (Duncanson et al., 2019; Jucker et al., 2017).

85
86 4) Spaceborne Light Detection and Ranging (Spaceborne LiDAR) (e.g. GEDI, ICESat, and ICESat-2) can provide
87 estimates of forest height in non-continuous footprints of tens to hundreds of metres, underpinning most large-scale
88 AGB maps, particularly in the lowland tropics (Avitabile et al., 2011; Avitabile et al., 2016; Saatchi et al., 2011).
89 Various satellite missions have also provided empirical evidence for correlations between the radar signal and AGB
90 for AGB < 250 Mg ha⁻¹ (Askne and Santoro, 2012), but the ESA BIOMASS mission, launched on the 29th of April
91 2025, is the only mission specifically targeting higher biomass tropical forests (Quegan et al., 2019; Ramachandran
92 et al., 2023).

93
94 The current challenge is to consistently collect and process plot-based measurements in support of EO-derived AGB, combine
95 them, integrate them with long-term ground-based inventory approaches, and optimally use them with EO data. There is
96 increasing recognition that the value of large-scale EO approaches to assessing AGB and forest structure largely depends on
97 robust calibration and validation data (Duncanson et al., 2019; Nature Editorial, 2022; Ochiai et al., 2023). This knowledge
98 and capability gap have led to calls for concerted international funding and coordination to establish long-term Forest Biomass
99 Reference Measurement Sites (FBRMS), with a particular focus on tropical forests (Labrière et al., 2023; Schepaschenko et
100 al., 2019).

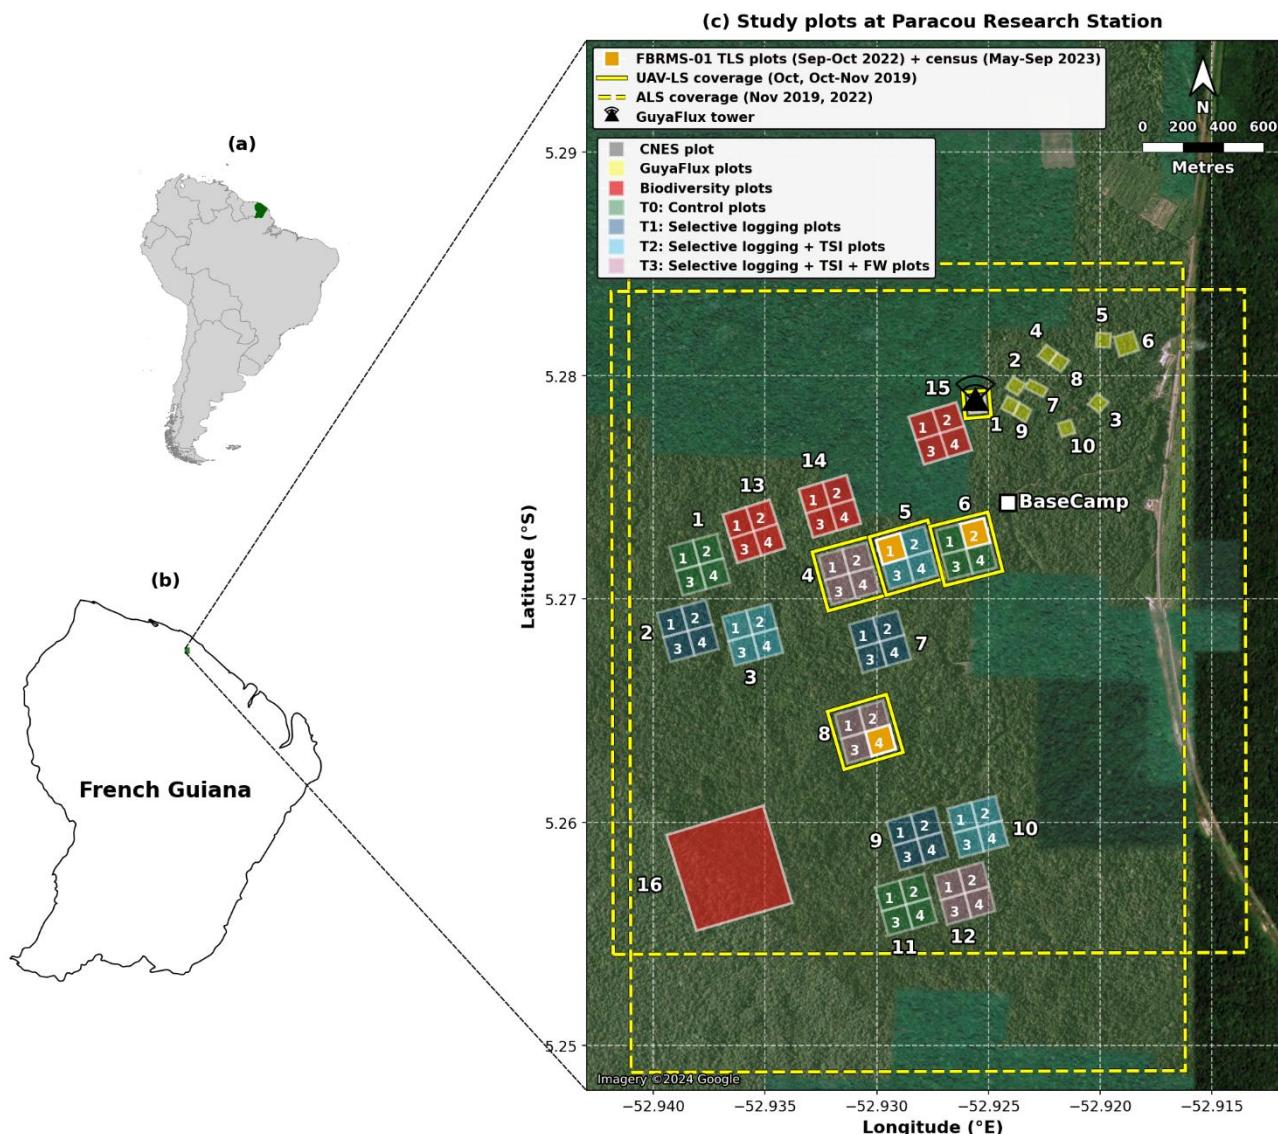

101
102 Here, we present a new dataset from the European Space Agency (ESA) funded ForestScan project, which contributes to this
103 aim and provides access to data from the first three FBRMS of the GEO-TREES network. The project has collected data,
104 including TLS, UAV-LS, ALS, and census data, covering three FBRMS across the tropics. We describe these data, related
105 data collection and processing protocols and tools, and make brief recommendations for future data collection for FBRMS.

106 **2. Methodology**

107 **2.1 ForestScan Forest Biomass Reference Measurement Sites (FBRMS)**

108 Three Forest Biomass Research Monitoring Sites (FBRMS) were selected based on various criteria, including the availability
109 of well-established plots, the representativity of tropical forest types and climates, established collaborations, agreements and
110 logistical support with in-country partners, and the availability of previously collected data, particularly census data, as well
111 as ALS and TLS data. The chosen sites were:

112 • FBRMS-01: Paracou Research Station, French Guiana
113 • FBRMS-02: Station d'Etudes des Gorilles et Chimpanzés, Lopé National Park, Gabon
114 • FBRMS-03: Kabili-Sepilok, Malaysian Borneo

117 **Figure 1:** Multi-scale map depicting the location and spatial distribution of research plots at Paracou Research Station, French
 118 Guiana. (a) Location of French Guiana (green) within South America. (b) Location of Paracou Research Station (green) within
 119 French Guiana. (c) Detailed site map showing the spatial distribution of research plots with treatment-specific colours, UAV-
 120 LS coverage (yellow solid outline), and ALS coverage (yellow dashed outline). The map displays 15 experimental 4 ha plots,
 121 each containing four 1 ha subplots numbered 1 - 4 (60 subplots in total; plots 1 - 12: silvicultural treatments; plots 13 - 15:
 122 Biodiversity monitoring), one large 40 ha Biodiversity plot (plot 16; red), and 10 GuyaFlux plots (yellow). Treatment
 123 categories include: Biodiversity monitoring plots (plots 13, 14, 15, 16; red), T0 Control (plots 1, 6, 11; green), T1 Selective

124 logging (plots 2, 7, 9; dark blue), T2 Selective logging + thinning by timber stand improvement (TSI; plots 3, 5, 10; cyan), and
125 T3 Selective logging + TSI + fuelwood harvesting/FW (plots 4, 8, 12; pink). The three FBRMS-01 subplots -FG5c1 (subplot
126 1 of plot 5), FG6c2 (subplot 2 of plot 6), and FG8c4 (subplot 4 of plot 8)- are shown in solid orange and were surveyed using
127 terrestrial laser scanning (TLS) with corresponding tree census data. The GuyaFlux tower location is indicated by a black
128 triangle with radiating transmission waves, and the Base Camp location is marked with a white square. Scale bar: 800 m. Map
129 data: Natural Earth 10 m cultural vectors. Satellite imagery basemap: Imagery ©2024 Google. Map projection: WGS84
130 (EPSG:4326).

131

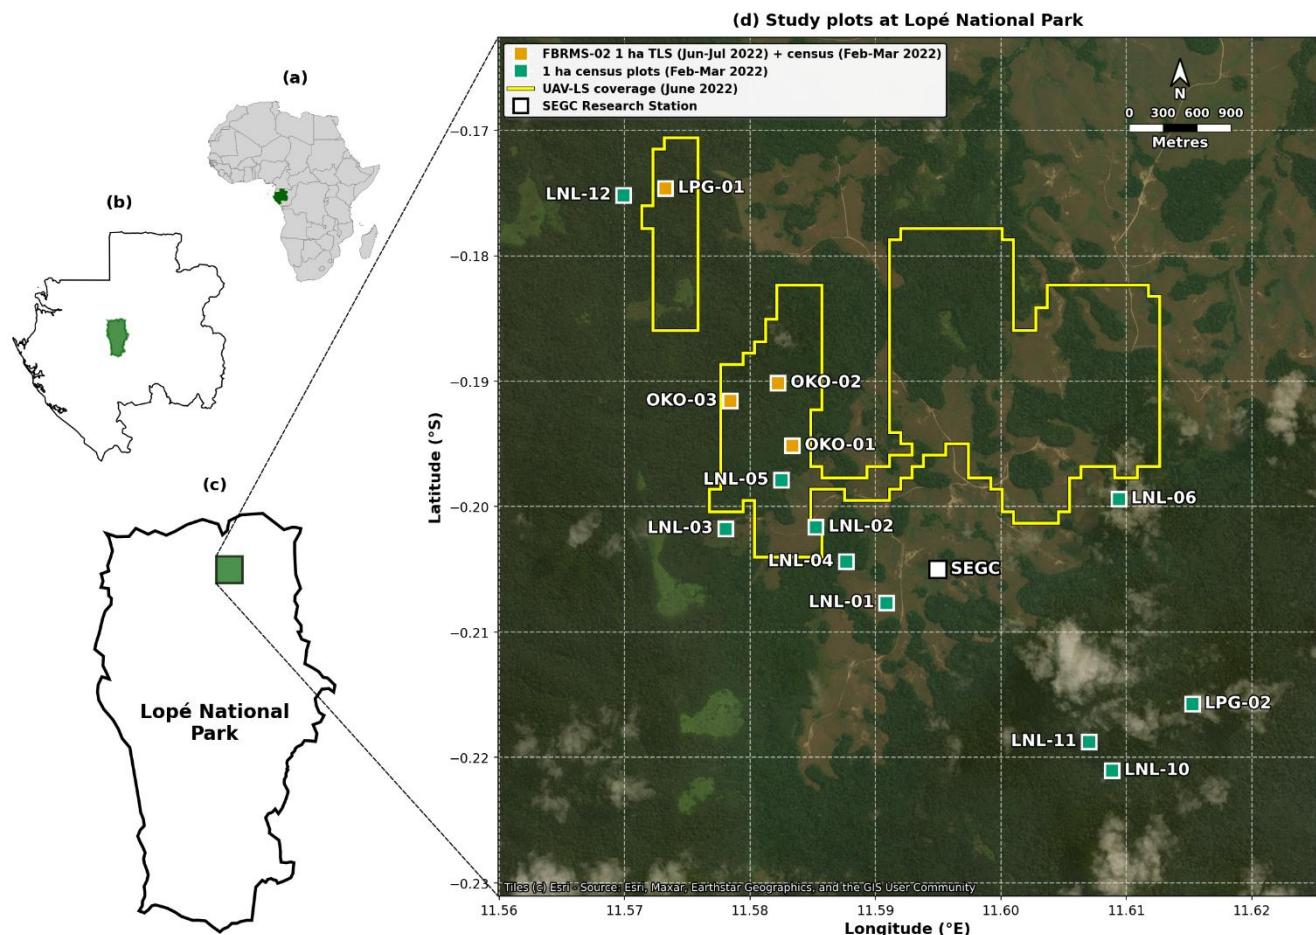

132 The Paracou research station is located near Sinnamary in the northern part of French Guiana, at a latitude of 5°18'N and a
133 longitude of 52°53'W. It is established on a long-term concession of the French National Centre for Space Studies (CNES)
134 and is managed by Centre de Coopération Internationale en Recherche Agronomique pour le Développement-Unité Mixte de
135 Recherche Écologie des Forêts de Guyane (Cirad-UMR EcoFoG). The station experiences an equatorial climate characterised
136 by two main climatic periods: a well-marked dry season from mid-August to mid-November and a long rainy season, often
137 interrupted by a short drier period between March and April. The station receives approximately 3,000 mm of rainfall annually
138 (mean annual precipitation from 2004 to 2014: 3,102 mm) and has a mean annual temperature of 25.7°C.

139

140 The core area of the Paracou research station (approximately 500 ha) is predominantly covered by lowland terra firme
141 rainforest. This old-growth forest has experienced no major human disturbance, although there are signs of pre-Columbian
142 activities. Species richness is high, with more than 750 woody species recorded, and 150 - 200 tree species per hectare with
143 DBH above 10 cm. A few dominant botanical families characterise the vegetation: Fabaceae, Chrysobalanaceae,
144 Lecythidaceae, Sapotaceae, and Burseraceae. The local heterogeneity of the floristic composition is mainly driven by soil
145 drainage. AGB, measured on trees with a DBH \geq 10 cm, ranges from 286.10 to 450 Mg/ha.

146

147 Following an initial inventory in the early 1980s, 12 permanent 6.25 ha plots were established in 1984. Plot corners, perimeters,
148 and inner trails (defining four subplots) were verified \sim 10 years later by a professional land surveyor. Nine plots were logged,
149 and six received additional silvicultural treatments between 1986 and 1988, creating a disturbance gradient with AGB losses
150 of 18–25% (treatment 1), 40–52% (treatment 2), and 48–58% (treatment 3). In the early 1990s, three more 6.25 ha plots and
151 one 25 ha plot were added, totalling \sim 120 ha of forest censused annually (controls), biennially (disturbed plots), or every five
152 years (25 ha plot). All 6.25 ha plots are subdivided into four subplots (see Fig. 1), with relative tree coordinates recorded. Trees
153 and palms \geq 10 cm DBH are mapped, identified, tagged, and periodically measured, forming a database of $>70,000$ trees. Since
154 2003, a 57 m flux tower has measured greenhouse gas fluxes, and an N, P, NP fertilisation experiment has been ongoing since
155 2015.

158 **Figure 2:** Multi-scale map showing the location and spatial distribution of research plots within Lopé National Park,
 159 Gabon. (a) Location of Gabon (green) within Africa. (b) Location of Lopé National Park (green) within Gabon.
 160 (c) Park boundary showing the research site location (green). (d) Detailed site map showing the spatial distribution of 14 one-hectare
 161 research plots. The four ForestScan FBRMS-02 plots (LPG-01, OKO-01, OKO-02, OKO-03; orange squares) were scanned
 162 using TLS during Jun-Jul 2022 with tree census data collected during Feb-Mar 2022. Tree census data was also collected for
 163 another ten plots (green circles) which are not part of the ForestScan project. Yellow outlined areas indicate coverage of
 164 UAV-LS conducted in Jun 2022. The SEGC (Station d'Études des Gorilles et Chimpanzés) research station is marked with a
 165 white square. Map data: Natural Earth 10m cultural vectors. Satellite imagery basemap: Esri World Imagery (Esri, Maxar,
 166 Earthstar Geographics, and the GIS User Community). Map projection: WGS84 (EPSG:4326).

168 Lopé National Park is a 5000 km² protected area in central Gabon (Latitude 0°30'S and Longitude 11°30'E), comprising predominantly intact old-growth moist tropical forest. The northern part of the park
 169 features a savanna-forest mosaic, an anthropogenically maintained remnant of the landscape from the Last Glacial Maximum.
 170 The broader landscape is designated as a UNESCO World Heritage Site.

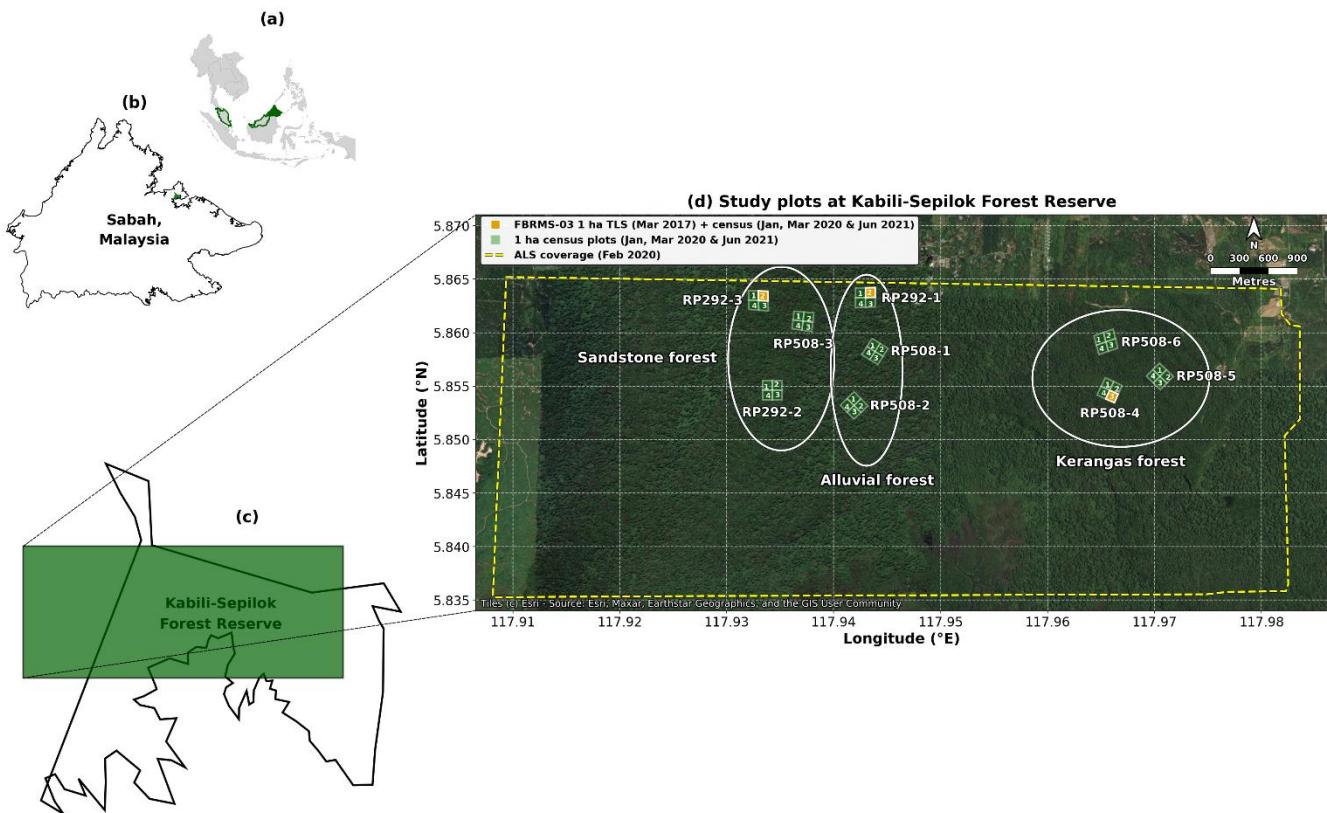

172

173 The transition from savanna to old-growth forest in the northern part of the park is characterised by six distinct forest types
 174 (Cuni-Sanchez et al., 2016; White et al., 1995): (i) savanna, (ii) colonising forest, (iii) monodominant Okoume forest, (iv)
 175 young Marantaceae forest, (v) mixed Marantaceae forest, and (vi) old-growth forest.

176

177 A substantial and varied body of literature has emerged from research conducted in Lopé National Park (Agence Nationale
 178 Des Parcs Nationaux, 2025). More than 100 long-term censused forest plots have been established within the park, contributing
 179 significant ground data for the calibration and validation of EO instruments (i.e. Duncanson et al., 2022; Saatchi et al., 2019).
 180 These plots also support various other research activities, such as the Global Ecosystem Monitoring (GEM) Network, an
 181 initiative aimed at understanding forest ecosystem functions and traits (Malhi et al., 2021).

182 **BRMS-03: Kabilis-Sepilok, Malaysian Borneo**

183

184 **Figure 3:** Multi-scale map showing the location and spatial distribution of research plots at Kabilis-Sepilok Forest Reserve,
 185 Sabah, Malaysian Borneo. (a) Location of Sabah (green) within Malaysia (green boundary) in Southeast Asia.
 186 (b) Location of the Kabilis-Sepilok Forest Reserve (green) within Sabah. (c) Kabilis-Sepilok Forest Reserve area and site map area of panel
 187 d (green rectangle). (d) Detailed site map showing the spatial distribution of 9 x 4 ha plots (labelled RP291-1, RP292-3, etc.)

each containing four 1 ha subplots numbered 1 - 4 (36 subplots in total; green polygons with white subplot numbers) across three soil types: Alluvial forest, Sandstone forest, and Kerangas forest (delineated by black ellipses). The three FBRMS subplots are SEP-11 (subplot 2 of plot RP292-3, sandstone soil), SEP-12 (subplot 2 of plot RP292-1, alluvial soil) and SEP-30 (subplot 3 of plot RP508-4, kerangas soil). Three ForestScan FBRMS-03 1 ha subplots (orange squares) were scanned using TLS during March 2017 and tree census for all subplots was collected in Jan, Mar of 2020 and Jun 2021. Yellow dashed outline indicates ALS coverage acquired in February 2020. Scale bar: 1000 m. Map data: Natural Earth 10m cultural vectors. Satellite imagery basemap: Tiles ©Esri - Source: Esri, Maxar, Earthstar Geographics, and the GIS User Community. Map projection: WGS84 (EPSG:4326).

The Kabili-Sepilok Forest Reserve is located on the Sandakan Peninsula in North-East Sabah, Malaysia, and encompasses approximately 4,300 hectares of intact old-growth tropical forest. Sepilok has been protected since its establishment by the Sabah Forest Department in 1931. The elevation ranges from 50 to 250 metres above sea level. This topographic variation, combined with edaphic differences, results in three distinct forest types: (i) lowland mixed dipterocarp forest overlaying alluvial soil in the valleys, (ii) sandstone hill forest on hillsides and crests, and (iii) lowland mixed dipterocarp and kerangas forest at higher elevations (Sabah Forestry Department, n.d.).

Between 1995 and 2000, the Ecology Section of the Sabah Forestry Department established 36 one-hectare censused forest stands across these forest types, as illustrated in Fig. 3.

2.2 Data

2.2.1 Tree census

Quality-controlled, tree-by-tree data on identity (tag number and species) and diameter size for all sampled plots in each of the three FBRMS were collected using global standard tropical forest plot inventory protocols (Forestplots.Net et al., 2021). This ensured a consistent, full species-level census for all plot trees with a diameter equal to or greater than 10 cm at each FBRMS. Censuses provide tree-by-tree records that can potentially be linked to laser-scanning approaches. Species identity plays a key role in determining tree biomass through its strong influence on wood density. While laser-scanning techniques provide excellent measurements of tree dimensions (such as height and volume), they still require wood density estimates to convert these volumes into accurate biomass values (see Goodman et al., 2014). Census data also provide tree-by-tree measurements of tree diameter and whole forest basal area. Finally, because they are independent of constantly changing sensor technologies, when sustained over time, the core measurement protocols in forest plots deliver long-term consistency for tracking forest biomass change, growth, mortality, demography, and their trends over decades.

Census data for FBRMS plots in Gabon and Malaysia are available via ForestPlots.net (<https://forestplots.net/>, Forestplots.Net et al., 2021; Lopez-Gonzalez et al., 2011). ForestPlots.net is an internet-based facility with functionality to support all aspects of forest plot data management, including archiving, quality control, sharing, analysis, and data publishing via stable URLs (DOIs). ForestPlots.net currently supports the data management needs of more than 2,000 contributors working with 7,000

222 plots across 23 participating tropical networks. Data access requires potential users to provide details of their planned use and
223 agreement to abide by requirements for the inclusion of all contributing researchers. This encourages maximum inclusivity of
224 data originators and is recognised as a key part of what is required to maintain long-term investment in people and infrastructure
225 that enables continued measurements in these areas (De Lima et al., 2022).

226 **Tree census: FBRMS-01: Paracou, French Guiana**

227 In the Paracou FBRMS, tree censuses are conducted by two teams of three to five permanent field staff using Qfield on field
228 tablets (since 2020, field computers were used prior to this). Tree girth is measured with a measuring tape at 1.3 m, except
229 when buttresses necessitate a higher measurement point. The point of measurement (POM) is marked with paint to ensure the
230 exact same point of measurement between censuses. POM and its potential changes are recorded. New recruits -trees that have
231 grown beyond 10 cm DBH since the previous survey- are recorded by the field team using vernacular names, and their positions
232 are measured relative to the original trees. To ensure accurate identification, periodic botanical campaigns are conducted by
233 one or two experienced botanists, who also correct any misidentifications. When species cannot be identified in the field,
234 samples are collected and examined at the EcoFoG herbarium in Kourou or the IRD herbarium in Cayenne. All identifications
235 follow the Angiosperm Phylogeny Group (APG) IV plant classification system. Dead trees and the cause of their death are
236 recorded. Data are checked for errors after field census using an R script. Any abnormal measurement (e.g., girth showing
237 abnormal increase/decrease, missing value) is then rechecked in the field in the weeks following the initial census.

238
239 Plot descriptions for the Paracou FBRMS plots FG5c1, FG6c2 and FG8c4 are accessible via the Guyafor DataVerse
240 (<https://dataVERSE.cirad.fr>). This internet-based data repository provides plot descriptions and datasets downloadable as CSV
241 files, together with the corresponding metadata (Derroire et al., 2023). The ForestScan Project data package, including the
242 latest tree census data used in our analysis and collected in August 2023 for FBRMS plot FG5c1, in June 2023 for plot FG6c2,
243 and in September 2023 for plot FG8c4, is accessible via
244 <https://dataVERSE.cirad.fr/dataset.xhtml?persistentId=doi:10.18167/DVN1/94XHID> (Derroire et al., 2025).

245 **Tree census: FBRMS-02: Lopé, Gabon**

246 In the Lopé FBRMS, tree census data was collected at 12 plots in 2017 for the ESA AfriSAR campaign. During June - July
247 2022, these 13 plots plus one additional 1 ha plot (LPG-02) were re-censused, making a total of 11 x 1 ha forest plots, plus 3
248 x 1 ha plots in savanna (see Fig. 2). The 10 ha plots included LPG-01, OKO-01, OKO-02 and OKO-03, the 4 x 1 ha FBRMS
249 plots where TLS was conducted in 2017 and 2022.

250 **Tree census: FBRMS-03: Kibili-Sepilok, Malaysian Borneo**

251 In the Kibili-Sepilok FBRMS, tree census data was collected during 2020 - 2022 for a total of 9 x 4 ha plots (IDs RP291-1,
252 RP292-3, etc. see Fig. 3) each containing four 1 ha subplots numbered 1 – 4 and covering most of the long-term plots at this

253 site. The three FBRMS subplots SEP-11 (subplot 2 of plot RP292-3, sandstone soil), SEP-12 (subplot 2 of plot RP292-1, 254 alluvial soil) and SEP-30 (subplot 3 of plot RP508-4, kerangas soil) were scanned using TLS during March 2017 and tree 255 census for all subplots was collected in Jan, Mar of 2020 and Jun 2021. The 2020-2022 census was overdue as these plots had 256 not been censused since 2013.

257
258 Plot meta-data, including geography, institution, personnel and historical context, as well as tree-level census attributes (tag, 259 identity, diameter, point of measurement, stem condition, height, sub-plot, and, where measured x, y coordinates of 5 x 5 m 260 subplots) and multi-census attributes (tree demography and measurement trajectory and protocols, including growth, point of 261 measurement changes, recruitment, mortality, and mortality mode) were recorded for all Gabonese and Malaysian FBRMS 262 plots.

263
264 The ForestScan Project data package, includes data from the 2022 tree census collected during February and March for the 265 Gabon FBRMS plots and the Malaysian FBRMS plots census data collected in October 2020 for FBRMS plot SEP-11, in 266 March 2020 for plot SEP-12, and in June 2021 for plot SEP-30. This data package can be accessed via 267 https://doi.org/10.5521/forestplots.net/2025_2 (Chavana-Bryant et al., 2025).

268 **2.2.2 Terrestrial Laser Scanning (TLS)**

269 TLS data was collected to provide state-of-the-art estimates of tree- and stand-scale AGB for each FBRMS. These LiDAR 270 measurements, collected using the protocol described in the following sections, produce 3D point clouds with millimetre-level 271 accuracy representing the forest at each FBRMS. TLS chain sampling protocols (Wilkes et al., 2017), as illustrated and 272 described in Fig. 4, were employed at all three FBRMS. This data was processed to construct explicit Quantitative Structural 273 Models (QSMs) describing individual trees within each FBRMS with a DBH ≥ 10 cm. Tree- and stand-scale AGB estimates 274 were then calculated from the volumes of these models, using wood density values derived from published sources based on 275 species identification from botanical surveys.

276
277
278
279
280
281
282
283
284
285

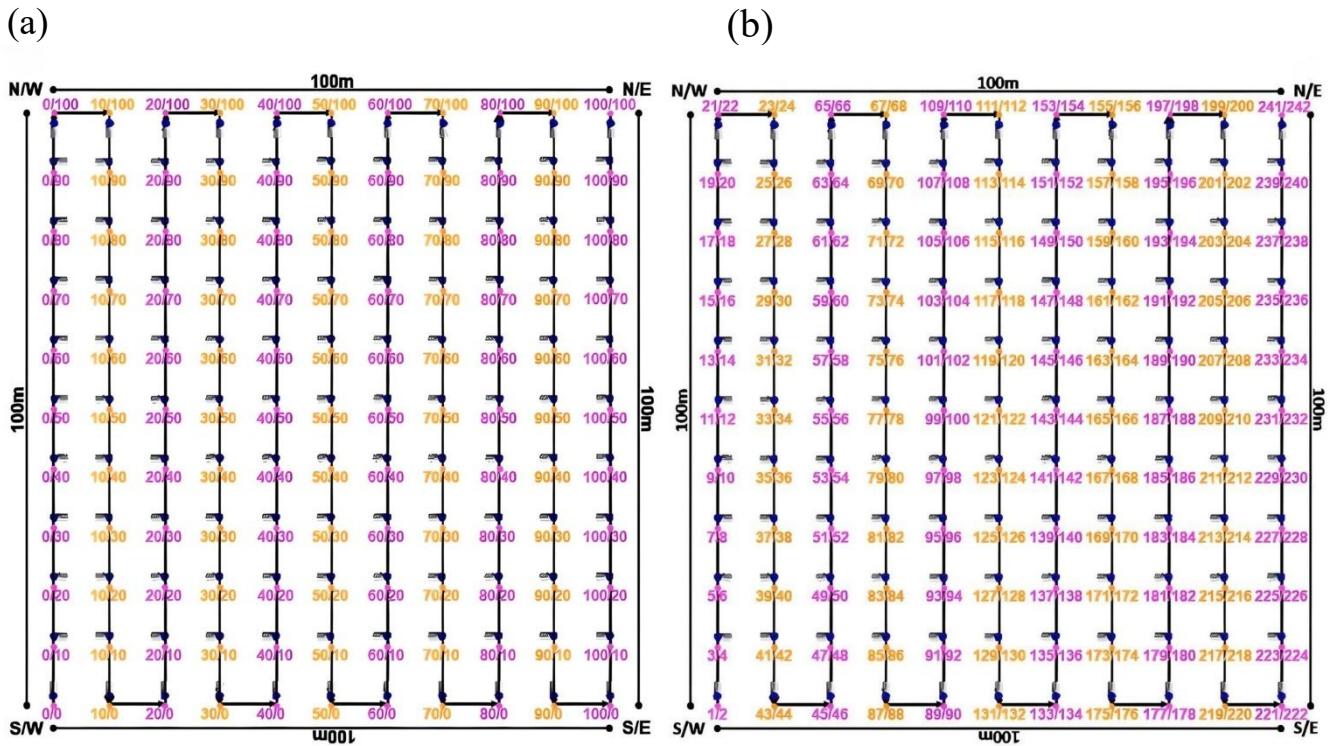

Figure 4: TLS chain sampling was employed to capture high-quality LiDAR data suitable for accurate tree- and stand-scale AGB estimation. Chain sampling was deployed over a 10 m Cartesian grid, resulting in 11 sampling lines with 11 scan positions along each line (i.e., 0 – 10) within 1 ha forest plots. Sampling lines were established in a south-to-north direction (standard practice) and colour-coded using flagging tape, with the ID of each scan position written in permanent marker. Scan positions were identified by their line number and grid position, as shown in panel b (left). Due to the scanner's 100° field of view, capturing a complete scene at each scan position required two scans—upright and tilted. Consequently, 242 scans were collected from 121 positions at each 1 ha forest plot. The order in which the 242 individual scans were collected at each plot is depicted in panel b (right). The first scan at each plot was collected at the southwest corner, i.e., scan position 0,0 (unless impeded by obstacles such as streams, large tree falls, etc., or if the plot was oriented differently). To facilitate scan registration, all tilt scans along the first sampling line were oriented towards the same sampling position along the next sampling line, and all other tilt scans along plot edges were oriented towards the inside of the plot so that the previous scan location was within the tilt-scan field of view. Depending on the density of the canopy understory, terrain, and wind conditions (ideally, low to zero wind and no rain or mist/fog), a team of three experienced TLS operators required 1–2 full working days (8 hrs per day) to set up the chain sampling grid and 3–5 full days to complete the scanning of a 1 ha plot.

304 Kinematic (RTK) positioning (RIEGL Laser Measurement Systems GmbH, 2025). RTK GNSS facilitates TLS data acquisition
 305 by replacing the labour-intensive and time-consuming task of placing and continuously relocating retro-reflective targets
 306 between scan positions as required by the RIEGL VZ-400 scanner. Common targets between adjacent scan locations were
 307 later identified and used to create a registration chain that integrates the 3D point cloud of a scanned plot. GNSS RTK has
 308 replaced the use of common targets, enabling the absolute (latitude, longitude, and altitude) and relative (between base and
 309 rover GNSS) positioning of individual scans with centimetre precision, which makes the auto-registration of scans in real-time
 310 possible. This GNSS-enabled auto-registration significantly reduces the time and effort required to both collect and register
 311 TLS data. Furthermore, data collected with the VZ-400i are backwards compatible with data from the older VZ-400 scanner,
 312 allowing for consistent processing and comparison over time.

313

314 **Table 1:** RIEGL laser scanners (RIEGL Laser Measurement Systems GmbH, 2025) and user-defined characteristics for TLS
 315 data acquisition at ForestScan FBRMS.

Characteristic	RIEGL VZ-400	RIEGL VZ-400i
Wavelength [nm]	~1550 (near-infrared)	~1550 (near-infrared)
Ranging accuracy / precision [mm]	5 / 3	5 / 3
Max range [m]	~800 @ 80% reflectivity	~800 @ 80% reflectivity
Beam divergence [mrad]	0.35	0.35
Beam diameter at emission [mm]	7	7
Returns per pulse	Up to 7	Unlimited (waveform)
GNSS RTK positioning	No	Yes (integrated)
Max Pulse Repetition Rate [kHz]	300 – 1200 (300 used)	300 – 1200 (300 used)
Angular resolution	0.04° with 22.4 million emitted pulses per scan (5.42 billion per hectare)	0.04° with 22.4 million emitted pulses per scan (5.42 billion per hectare)
FOV [°]	360 (horizontal) 100 (vertical)	360 (horizontal) 100 (vertical)
Scan time per scan	3 minutes	3 minutes
Weight [kg]	~13	~13
Operated by	UCL	UCL
Scan site (s)	FBRMS-03: Malaysia	FBRMS-01: French Guiana FBRMS-01: Gabon

317 **TLS: FBRMS-01: Paracou, French Guiana**

318 TLS data was collected in Paracou over two separate periods due to interruptions caused by the COVID-19 pandemic. The
 319 first campaign took place in 2019, censused plot FG6c2 was scanned with a RIEGL VZ-400 scanner during October and
 320 November (Brede et al., 2022a). The scanning was conducted over a 200 x 200 m² area (i.e. two 1 ha plots) covering two of
 321 plot 6 subplots -2 and 4- (see Panel c in Fig. 1), resulting in 21 x 21 scan lines with 10 m grid spacing. Retro-reflective targets
 322 were placed between scan positions to facilitate coarse registration (Wilkes et al., 2017).

323

324 The second TLS campaign took place in 2022, three 1 ha censused plots (see Fig. 1) were scanned during September and
 325 October using a RIEGL VZ-400i scanner with GNSS RTK-enabled auto-registration. These plots were selected to represent
 326 the disturbance gradient found at this site, as shown in Table 2. All three plots were also scanned with ALS and plot FG6c2
 327 additionally scanned with UAV-LS.

328

329 **Table 2:** Overview of plots scanned in 2022 with TLS in Paracou, French Guiana. We provide both ForestScan plot IDs and
 330 their corresponding census plot and subplot IDs used by the census internet-based data repositories.

Plot ID	Census Plot / Subplot ID	Logging treatment	Description	AGB	Lat	Long
FG6c2	6 / 2	Control	Old-growth, lowland, Terra firme rainforest	High	5.27	-52.92
FG5c1	5 / 1	T2	Old-growth, lowland, Terra firme rainforest with mid-level logging disturbance	Mid	5.27	-52.92
FG8c4	8 / 4	T3	Old-growth, lowland, Terra firme rainforest with high-level of logging disturbance	Low	5.26	-52.93

331

332 **TLS: FBRMS-02: Lopé, Gabon**

333 TLS data was collected in 2022, four 1 ha plots were scanned using a RIEGL VZ-400i with GNSS RTK-enabled auto-
 334 registration, eliminating the need for retro-reflective targets between scan positions. The four sampled plots, shown in Table
 335 3, were selected to represent the diversity of forest types found within this site.

336

337 **Table 3:** Overview of plots scanned with TLS in Lopé National Park, Gabon. We provide both the ForestScan plot IDs and
 338 their corresponding census plot and subplot IDs used by the census internet-based data repositories.

Plot ID	Census Plot ID	Description	Lat	Long
OKO-01	LNL-07	Maturing secondary Okoum�� forest	-0.19	11.58
OKO-02	LNL-08	Maturing secondary Okoum��-Sacoglottis forest	-0.19	11.58
OKO-03	LNL-09	Maturing secondary Okoum�� forest	-0.19	11.57
LPG-01	LPG-01	Old-growth forest	-0.17	11.57

339

340 **TLS: FBRMS-03: Kabili-Sepilok, Malaysian Borneo**341 TLS data was collected for three 1 ha forest plots at this FBRMS during March 2017. The three sampled plots, shown in Table
342 4, were selected to represent the three distinct forest types found within this site. A RIEGL VZ-400 scanner was used, with
343 retro-reflective targets positioned between scan locations to facilitate coarse registration (Wilkes et al., 2017).

344

345 **Table 4:** Overview of plots scanned with TLS in Kabili-Sepilok Forest Reserve, Malaysia. We provide both the ForestScan
346 plot IDs and their corresponding census plot and subplot IDs used by the census internet-based data repositories.

Plot ID	Census Plot / Subplot ID	Description	Lat	Long
SEP-11	RP292-3 / 2	Sandstone forest	5.86	117.94
SEP-12	RP292-1 / 2	Alluvial forest	5.86	117.93
SEP-30	RP508-4 / 3	Kerangas forest	5.86	117.97

347

348 **TLS data processing**349 TLS data was collected and processed to provide state-of-the-art estimates of tree- and plot-scale structural attributes and AGB
350 for each ForestScan FBRMS. Five main processing steps are required to retrieve structural attributes from the acquired TLS
351 data are described below. These processing steps demand significant computational resources -a full 1 ha plot can take 3.4 to
352 4 days to process from start to finish on a high performance computing (HPC) cluster, running on multiple central processing
353 units (CPUs; general-purpose processors optimised for sequential tasks and complex logic) and graphics processing units
354 (GPUs; highly parallel processors ideal for deep learning, point cloud processing and simulations tasks that can be broken into
355 thousands of simultaneous operations).

356

357 **1. Individual scan registration into plot-level point cloud**

358 This process was carried out using retro-reflective targets positioned between scan locations to facilitate coarse registration for
359 data collected with the RIEGL VZ-400 or in a near-automated manner using the RIEGL VZ-400i's GNSS RTK positioning
360 capabilities in conjunction with the enhanced RIEGL RiSCAN Pro software (versions 2.14–2.17). The integrated Auto
361 Registration 2 (AR2) function employs GNSS RTK data to update the scanner's position and orientation, including in tilt
362 mode, thereby enabling real-time automated coarse registration during scanning without the use of retro-reflective targets.
363 Major registration errors are easily detected, typically occurring during pre-processing in RiSCAN Pro when individual scans
364 fail to register (i.e., no coherent solution is found) or are incorrectly positioned, which is visually apparent. In cases where
365 coarse registration/auto-registration fails, unregistered scans can be identified, adjusted, and refined using Multi Station
366 Adjustment 2 (MSA2), which is also used for final precise registration of data initially coarse-registered using retro-reflective
367 targets. The registered plot point cloud is provided in the project's local coordinate system. Following this workflow, the co-
368 registration of all TLS point clouds achieves sub-centimetre accuracy, as confirmed through post-registration inspection. Wind
369 and occlusion are key sources of uncertainty for the scan registration process, highlighting the necessity of scanning under low
370 or zero wind conditions and capturing both tilt and upright scans at each location.

371

372 The use of GNSS significantly enhances the utility and accessibility of TLS by drastically reducing both data acquisition and
373 processing time. This is achieved by (1) as previously mentioned, replacing the previous labour-intensive and time-consuming
374 practice of using common retro-reflective targets to link adjacent scan positions into a registration chain (Wilkes et al., 2017),
375 and (2) reducing the manual processing registration time by an experienced user to 1 - 2 days per hectare, which is less than
376 half the time required when using retro-reflective targets.

377

378 Registration results in a plot-level point cloud, comprising 242 individual scan-level point clouds, potentially containing more
379 than 5.42 billion points.

380

381 The subsequent four processing steps were performed in a semi-automated manner using the *rxp-pipeline* (Wilkes and Yang,
382 2025a) and *TLS2trees* processing pipelines (Wilkes et al., 2023) and *TreeQSM* version 2.3 (Raumonen et al., 2013), as
383 described below.

384 **2. Pre-processing of plot-level point clouds**

385 Pre-processing is carried out in three steps using the open-source tool *rxp-pipeline* (Wilkes and Yang, 2025a), which operates
386 directly on the raw RIEGL scan data. First, the co-registered RIEGL point clouds are filtered to remove points with a deviation
387 greater than 15 and reflectance outside the range [-20, 5], The data are then clipped to the plot extent with an additional 20 m
388 buffer around the plot, segmented into 10 m x 10 m tiles, and converted from the RIEGL proprietary .rxp to .ply format to

389 enable further processing. Second, to reduce computing load, the tiled point clouds are downsampled using a voxelisation
390 approach with a voxel size of 0.02 m, implemented via *PDAL VoxelCenterNearestNeighbor* filter (PDAL Contributors, 2025).
391 Finally, a tile index mapping the spatial location of each tile is generated. In a HPC system, preprocessing of a 1 ha plot can
392 take 1.58 to 4.17 hours to complete.

393 **3. Semantic segmentation: wood-leaf separation**

394 *TLS2trees* is an open-source Python command-line pipeline (Wilkes et al., 2025) designed to automate tree extraction from
395 TLS point clouds by utilising GPUs for parallel computation, making it fully scalable on HPC systems (Wilkes et al., 2023).
396 The first of the two-step *TLS2trees* workflow employs a deep-learning based approach, implementing a modified version of
397 the Forest Structural Complexity Tool (FSCT) deep learning semantic segmentation method by Krisanski et al. (2021) to
398 classify points within tiled point clouds into homogeneous classes representing distinct biophysical components: leaf, wood,
399 coarse woody debris, or ground. An example of the wood and leaf classes extracted from tree-level point clouds is illustrated
400 in Fig. 5. In a HPC system, semantic segmentation of a 1 ha plot can take 4 to 12 hours to complete.

401

402 A comparison of the leaf-wood separation between *TLS2trees* and manual labelling showed a Jaccard index of between 54 -
403 87% across varying tropical sites (Wilkes et al., 2023). A number of TLS leaf-wood separation approaches have been
404 developed, using deep learning, or geometric approaches. Unsurprisingly, they all tend to perform worse for taller trees, higher
405 in the canopy (Arrizza et al., 2024). In *TLS2trees*, the impact of misclassifying (or missing) leaves, is to truncate smaller
406 branches (Wilkes et al., 2023), reducing the contribution to volume (and hence biomass). This tends to have less impact on tall
407 tropical trees, than on smaller more dense crowns of deciduous woodland (Calders et al., 2022).

408

409
410 **Figure 5:** Tree-level point cloud of the largest *Baillonella toxisperma* (Maobi) tree (~40 m tall with an almost circular

411 canopy ~50 m wide) in plot LPG-01, FBRMS-02: Lopé, Gabon. Points are classified and displayed by category only: wood
412 points in brown and leaf points in green.

413 **4. Instance segmentation: individual tree separation**

414 The second step in the *TLS2trees* workflow identifies and segments individual trees via a 2-step process. The Dijkstra's shortest
415 path method first groups all points identified as wood into a set of individual woody stems to which points identified as leaf
416 are then assigned. A small group of trees automatically segmented from a plot in Gabon are shown in Fig. 6. In a HPC system,
417 instance segmentation of a 1 ha plot can take 15-20 hours to complete.

418

419 **Figure 6:** Individual tree-level point clouds acquired from plot LPG-01 in FBRMS-02: Lopé, Gabon.

420 **5. TreeQSM: quantitative structural models and results**

421 Quantitative structural models (QSMs) were constructed in a near-automated manner from each individually segmented tree
422 point cloud (woody components only) with a DBH ≥ 10 cm within each ForestScan FBRMS plot. This was achieved using the

423 *TreeQSM* software package (version 2.3; Raumonen et al., 2013), which reconstructs underlying woody surfaces by fitting
424 cylinders, as illustrated in Fig. 7. The QSM fitting process involves three steps: (i) reducing each point cloud to a series of
425 patches, (ii) analysing the spatial arrangement and neighbour relationships among patches, and (iii) robustly fitting cylinders
426 to common patches.

427

428 The overall QSM fit is controlled by three parameters, which are iterated into 125 different parameter sets, each generating
429 five models. This yields a total of 625 candidate models per segmented tree. The optimal model is then selected by minimising
430 the point-to-cylinder surface distance (Burt et al., 2019; Martin-Ducup et al., 2021). Estimates of morphological and
431 topological traits such as volume, length, and surface area metrics, along with their mean and standard deviation, are derived
432 from the five models that share the same parameters as the optimal model. This approach provides an estimate of the
433 uncertainty associated with the resulting volume (Wilkes et al., 2023). In a HPC system, QSMs for a 1 ha plot can take up to
434 2 days to complete.

435

436

437

438 **Figure 7:** QSMs derived from individual tree-level point clouds acquired from plot LPG-01 in FBRMS-02: Lopé, Gabon.
439

440 Uncertainty estimates are reported for each ForestScan FBRMS plot and included alongside the final modelling outputs for
441 every tree in a ‘tree-attributes.csv’ file, generated at the end of the modelling process. Sources of error in QSM fitting can arise
442 from data acquisition (e.g., wind, leaf occlusion, understory vegetation) and from assumptions inherent in segmentation and
443 fitting processes. Wilkes et al. (2017) discuss issues related to data acquisition and methodological choices, while Morhart et
444 al. (2024) quantify their effects on branch size and volume under controlled conditions. Although these impacts are difficult
445 to assess without reference (harvest) data, Demol et al. (2022) show that, where TLS and harvest data have been compared,
446 agreement is generally within a few percent of AGB per tree. The report CVS file also includes tree- and plot-level carbon and
447 AGB estimates, the latter based on a mean pantropical wood density value of 0.5 g cm^{-3} derived from the DRYAD global
448 database of tropical forest wood density (2009). Plot-level AGB was also estimated using DRYAD-derived regional mean
449 wood densities and is presented in Table 5.

450
451 Figures of all individually segmented trees arranged by tree DBH size (largest to smallest DBH) are also generated for each
452 FBRMS plot, examples of which can be seen in Fig. 8. In a HPC system, tree figure for a 1 ha plot can take ~30 mins to
453 complete. Figure 9 provides a comparison of the distribution of DBH measurements collected by tree census and TLS methods
454 at each of the 10 ForestScan FBRMS 1 ha plots.

455 **TLS datasets**

456 The following terrestrial LiDAR-derived products are available for each of the 10 ForestScan FBRMS plots:

- 457 1. Raw terrestrial LiDAR data from each scan (no filtering was applied in RiSCAN PRO), stored in the RXP data stream
458 format developed by RIEGL.
- 459 2. Transformation matrices necessary for rotating and translating the coordinate system of each scan, into the coordinate
460 system of the first scan. Stored in DAT format.
- 461 3. Pre-processed terrestrial LiDAR data:
 - 462 a. full-resolution 10m tiled plot point clouds including attributes such as XYZ coordinates, scan position index,
463 reflectance, deviation, etc. stored in polygon PLY format.
 - 464 b. downsampled 10m tiled plot point clouds including attributes such as XYZ coordinates, scan position index,
465 reflectance, deviation, etc. stored in polygon PLY format.
 - 466 c. A tile_index file (maps the spatial location of the tiled point clouds) stored in DAT format.
 - 467 d. Bounding geometry files setting plot boundaries with and without a buffer surrounding the plot. Stored in
468 shapefile SHP, DBF, SHX and CPG formats.
- 469 4. Downsampled 10m tiled plot point clouds segmented into leaf, wood, ground points or coarse woody debris. Stored
470 in polygon file format PLY format.

471 5. Wood-leaf separated tree-level point clouds including segmentation results and classification probabilities for each
472 point are stored in polygon PLY format.

473 6. QSM files:

474 a. **in_plot** CSV (for plots processed with *TLS2trees*) lists all trees to be modelled with QSMs as they are located
475 inside the plot boundary.

476 b. **out_plot** CSV (for plots processed with *TLS2trees*) lists all trees NOT to be modelled as they are located
477 outside the plot boundary.

478 c. **plot_boundary** CSV (for plots processed with *TLS2trees*) shows the location of all in_plot trees within each
479 plot boundary.

480 d. **QSM processing files** (.MAT Matlab).

481 e. **QSMs** derived from each woody tree-level point cloud, (.MAT Matlab).

482 7. We provide pre-processed and segmented terrestrial LiDAR data in PLY format as it supports full 3D object
483 representation, including polygons and geometric primitives, in addition to point data. This is essential for storing
484 quantitative structure models (QSMs), which go beyond point clouds to describe tree geometry. The PLY format is
485 open, widely supported in Python and R, and can be converted to LAS/LAZ when only point data are required.

486 8. Tree-attributes file (.CSV) containing biophysical parameters derived from both the point clouds and QSMs: DBH,
487 tree height, tree-level volume and AGB with uncertainty, plot-level AGB and associated uncertainty.

488 9. Figures of all individually segmented trees arranged by tree DBH size (largest to smallest DBH) for each FBRMS
489 plot (see Fig. 8) (PNG image format).

490 10. GNSS coordinates (geographical coordinate system: WGS84 Cartesian) for all scan positions stored in KMZ zip-
491 compressed format. These files are available for the seven French Guiana and Gabon FBRMS plots.

492

493 These TLS ForestScan FBRMS 1 ha plot datasets are freely available via the Centre for Environmental Data Analysis (CEDA)
494 with URLs and DOIs provided in section 5, and are accompanied by the **ForestScan_example_directory_structure.pdf**
495 document for guidance on dataset organisation.

496 QSMs can be converted to PLY format using open-source tools such as *mat2ply* (Wilkes and Yang, 2025b) and then read by
497 various tools such as the widely-used free GUI tool CloudCompare (CloudCompare Development Team, 2025;
498 <https://www.cloudcompare.org>), via Python using PDAL (PDAL Contributors, 2025; <https://zenodo.org/records/4031609>) or
499 Open3D (Open3D Development Team, 2025; https://www.open3d.org/docs/0.9.0/tutorial/Basic/file_io.html#mesh), or via the
500 R Geomorph package (Adams et al., 2025; <https://rdrr.io/cran/geomorph/man/read.ply.html>). In the Geomorph R package, the
501 function Read mesh data (vertices and faces) from PLY files can be used to read three-dimensional surface data in the form of
502 a single PLY file (Polygon File Format; ASCII format, from 3D scanners). Vertices of the surface may then be used to digitise
503 three-dimensional points. The surface may also be used as a mesh for visualising 3D deformations, which refer to changes or

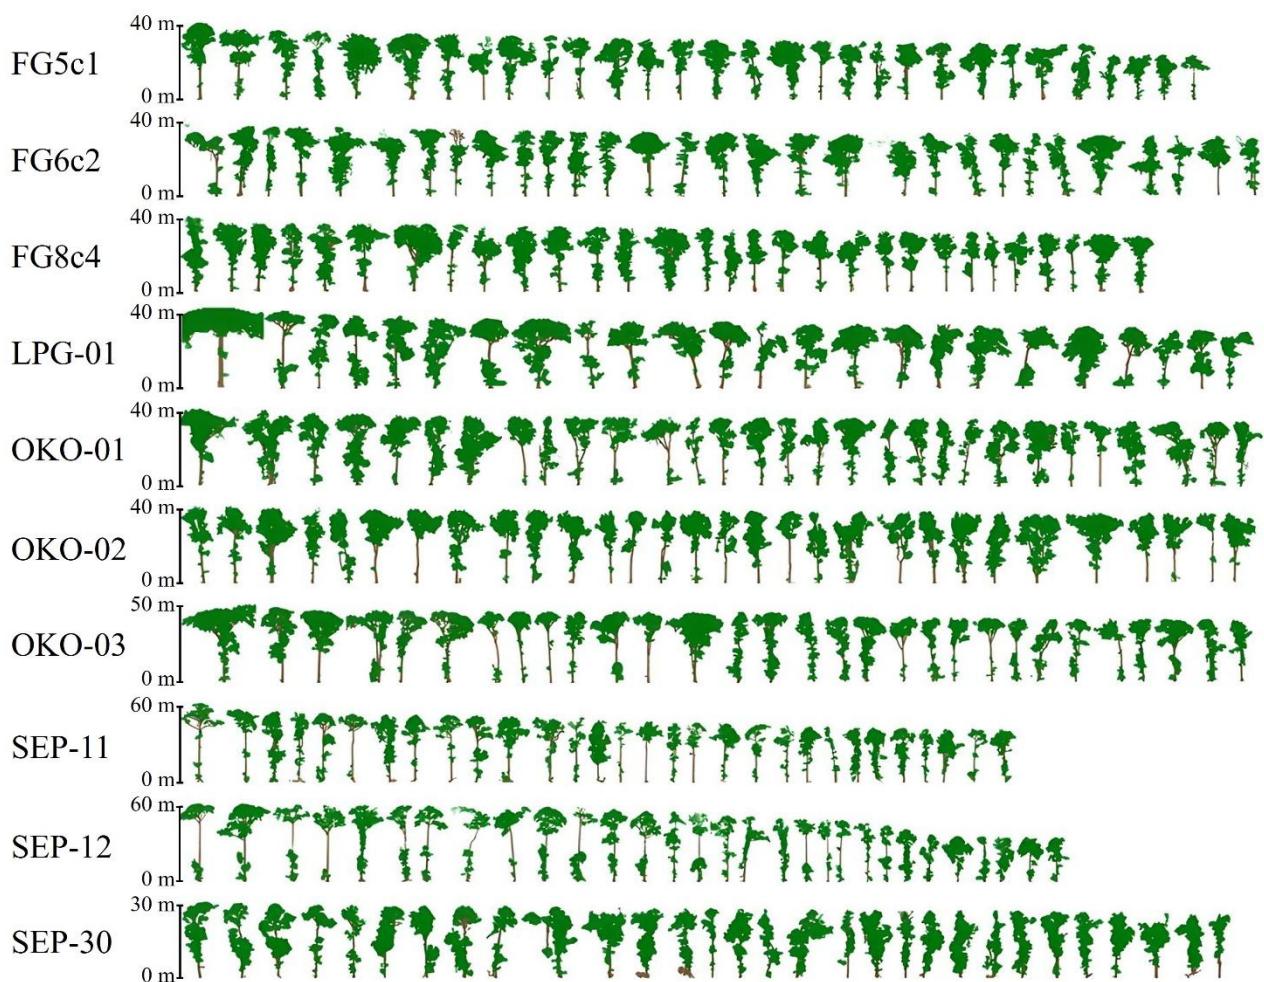

505 displacements in the geometry of the object compared to a reference state. This is achieved using the warpRefMesh function.
 506 The function opens the PLY file and plots the mesh, with faces rendered if file contains faces, and coloured if the file contains
 507 vertex colour. Vertex normals allow better visualisation and more accurate digitising with digit.fixed. The KMZ files
 508 containing the GNSS scan position coordinates can be uploaded to Google Earth or read into a GIS tool such as QGIS (QGIS
 509 Development Team, 2025; <https://qgis.org>).

510

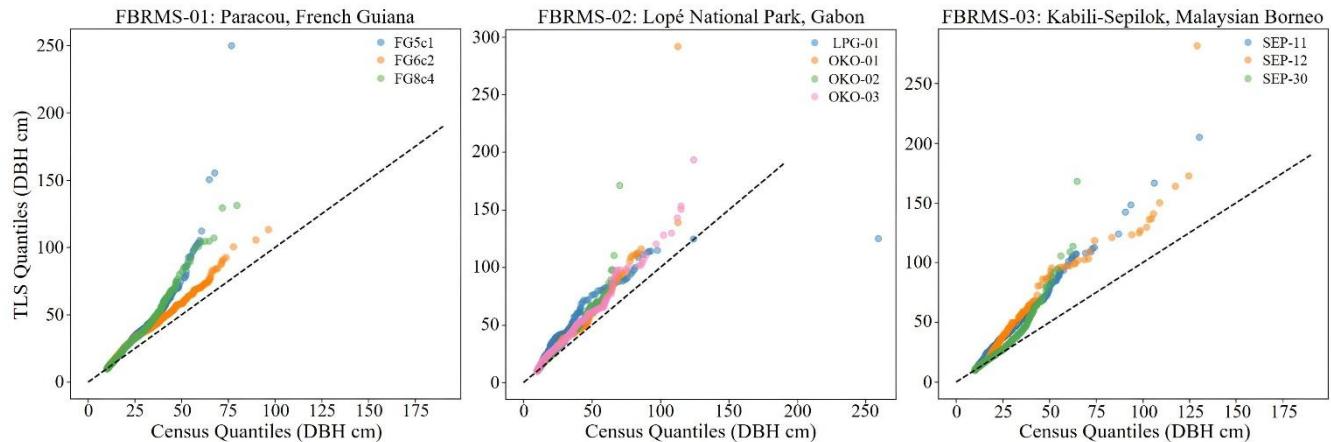

511 **Table 5:** Summary statistics for 10 FBRMS ForestScan TLS plot datasets. AGB estimates use wood density values from the
 512 DRYAD global database (Zanne et al., 2009): (1) *TLS2Trees* pantropical mean, (2) Tropical Africa mean (TAF, Gabon), (3)
 513 South-East Asia mean (TS-EA, Malaysia), (4) Tropical South America mean (TSA, French Guiana), (5) Guyana community
 514 mean (GF, French Guiana), and (6) allometric AGB estimates based on Chave et al. (2014).

518 **Figure 8:** Examples of the largest trees (up to 30 trees) arranged in decreasing DBH size (1.3 m trunk height) for each of the
519 10 ForestScan FBRMS plots. The upper limit of the Y axis varies and ranges from 30 m to 60 m maximum tree size between
520 plots.

521

522 **Figure 9:** Quantile-Quantile (QQ) plots comparing the distribution of DBH measurements collected by tree census and TLS
 523 methods at each of the 10 ForestScan FBRMS 1 ha plots. TreeQSM measures DBH at the standard height of 1.3 m for each
 524 TLS-extracted tree, whereas census DBH measurements are routinely adapted to account for tree buttresses found among
 525 larger trees. Generally, census and TLS DBH measurements are in good agreement but consistently overestimated by TLS.
 526 Deviations for larger DBH values can be improved by adapting the DBH extraction of large buttressed trees once these trees
 527 are matched to their census counterparts. The 1:1 reference line (dotted black line) represents perfect agreement between
 528 census and TLS-extracted DBH measurements.

529 **2.2.3 Unpiloted Aerial Vehicle laser scanning (UAV-LS)**

530 Unlike TLS, there are currently no best practice guidelines for UAV-LS data acquisition for forest characterisation. Therefore,
531 flight plans and parameters were implemented on a case-by-case basis, considering the site, instrument, sensor, and application.
532 An important consideration in this respect is whether VLOS needs to be maintained, i.e., the visibility of the platform by the
533 pilot throughout the mission. Regulations on this vary nationally and are changing rapidly as technology evolves and the use
534 of UAVs expands. In Europe, for example, a risk-based approach has been introduced, allowing beyond VLOS when risks are
535 negligible.

536

537 Another important consideration is the availability of take-off and landing areas. Vertical take-off and landing (VTOL)
538 platforms (e.g., quadcopters and octocopters) require smaller areas and are more flexible, while fixed-wing platforms may
539 require substantial take-off and landing sites, although they offer greater area coverage and flight duration. The actual take-off
540 area for VTOL platforms is highly dependent on the skills and confidence of the pilot. However, a very small take-off area
541 surrounded by tree crowns typically also means low chances for VLOS operation, unless an above-canopy platform such as a
542 cherry-picker is available.

543

544 In the context of VTOL and VLOS operations, viewshed analysis based on already acquired ALS data has proved useful. ALS
545 point clouds can be used to derive initial Digital Surface Models (DSM), which can identify possible take-off positions.
546 Viewshed analysis can then use the DSM to simulate the visibility of the UAV from the take-off position.

547

548 During data collection, attention should also be paid to acquiring access to GNSS observables from permanent base stations
549 (e.g., CORS network) or to collecting observables with a temporary base station (e.g., Emlid Reach RS+ or RS2). A base
550 station should be positioned less than 15 km from the survey area. For some platforms, Real-Time Kinematic (RTK), and
551 therefore radio connection, between the UAV and base station can be an added constraint.

552

553 Our UAV-LS data collections used three different LiDAR systems built by RIEGL at FBRMS-01 and FBRMS-02. All systems
554 are based on the time-of-flight principle and capable of multi-return registration with the miniVUX-1DL being a specific
555 downward-looking sensor designed for fixed-wing UAVs. Technical specifications for all three UAV-LS sensor systems are
556 provided in Table 6.

557

558 **Table 6:** UAV-LS sensor systems used at ForestScan FBRMS-01 and FBRMS-02.

Characteristic	miniVUX-1UAV	VUX-1UAV	miniVUX-1DL
Max Pulse Repetition Rate [kHz]	100	550	100

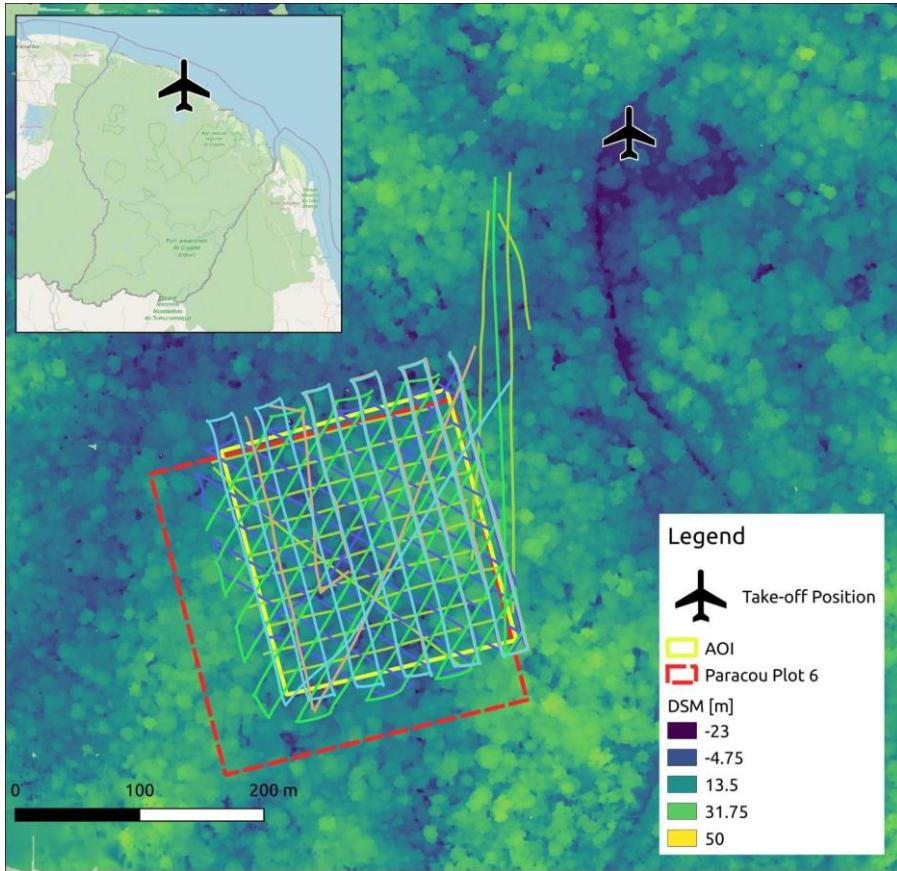

Wavelength [nm]	905	1550	905
FOV [°]	360	330	46
Ranging accuracy / precision [mm]	15 / 10	10 / 5	15 / 10
Max range [m]	330 @ $\rho \geq 80\%$	1050 @ $\rho \geq 80\%$	260 @ $\rho \geq 80\%$
Weight [kg]	1.55	3.5	2.4
Inertial Measurement Unit (IMU)	Applanix APX20	Applanix AP20	Applanix APX15
Operated by	AMAP	Wageningen University	University of Edinburgh
Operated on	DJI M600	RiCOPTER	DELAIR DT26X
Flight location	FBRMS-01: Paracou	FBRMS-01: Paracou	FBRMS-02: Lopé
Flights merged into single acquisition	No	No	Yes

559

560 **UAV-LS: FBRMS-01: Paracou, French Guiana**

561 UAV-LS data was collected in October 2019 using two different scanning systems as shown in Tables 7 and 8. The first set
 562 of 11 flights listed in Table 7 were conducted using the RIEGL VUX-1UAV mounted on a RIEGL RiCOPTER UAV and
 563 flown over the same 200 x 200 m² area that was scanned with TLS covering subplots 2 and 4 in plot 6. Six of these flights
 564 covered the entire 200 x 200 m² area with 20 m spacing between flight lines at an altitude of 120 m above ground level (AGL).
 565 The remaining five flights covered only the north-east 100 x 100 m² area covering subplot 2 (i.e. FG6c2) with a criss-cross
 566 pattern to maximise the diversity of viewing angles into the canopy. These latter flights were conducted at a lower altitude of
 567 90 m AGL to increase point density; however, the entire plot could not be covered without losing VLOS.

568

569

570 **Figure 10:** UAV-LS flight trajectories over the FBRMS-01 site at Paracou, showing coverage of the experimental 4 ha plot 6
 571 (red dashed outline) and the area of interest (AOI; yellow dashed outline). The criss-cross flight pattern results from multiple
 572 flight lines oriented in different directions (e.g., N–S, E–W, NE–SW) to improve point density and reduce occlusion in dense
 573 tropical forest canopies. The background shows a digital surface model (DSM) with elevation values (m), colour-coded by
 574 elevation classes as indicated in the figure legend (–23 m to 50 m). The inset map shows the regional location of Paracou
 575 within French Guiana (© OpenStreetMap contributors, available at <https://www.openstreetmap.org>).
 576

577

578 **Table 7:** Overview of the 2019 VUX-1 UAV-LS flights at FBRMS-01 (Paracou), including Census Plot ID (see Table 2),
 579 acquisition date/time, flight height above ground level (AGL), speed, and pulse repetition rate. Flight patterns refer to the
 580 orientation of flight lines: N–S (north–south), E–W (east–west), NE–SW (northeast–southwest), and “criss-cross” indicates
 581 multiple orientations flown over the same area as seen in Fig. 10. All flights listed can be considered part of one acquisition
 and are provided as individual point clouds in this dataset. Users may merge them according to their needs.

Census Plot ID	Date & Time (UTC ISO 8601)	Direction [°]	Interline [m]	Alt	Speed [m s ⁻¹]	Pulse Repetition Rate [kHz]
----------------	----------------------------	---------------	---------------	-----	----------------------------	-----------------------------

582

583 UAV-LS data was also collected over several plots using a different UAV-LS system -a YellowScan Vx20 containing a RIEGL
 584 Mini-VUX scanner and Applanix 20 IMU- mounted on a DJI M600. Details for a second set of 12 flights can be found in
 585 Table 8. To allow for comparisons with the VUX system, coincident acquisitions were performed over experimental plot 6
 586 (covering all four subplots) and several others within the Paracou Research Site (see Table 8).. A full description of the UAV-
 587 LS data collection for this UAV-LS data is provided in Brede et al. (2022b).
 588

589 **Table 8:** Overview of UAV-LS flights using a YellowScan Vx20 system (RIEGL Mini-VUX scanner and Applanix 20 IMU)
 590 mounted on a DJI M600 during the 2019 mission at the FBRMS-01 site. Automated flight plans were performed using flight
 591 plans with the UgCS route planning software in grid mode. The table lists plot ID, acquisition date/time, flight parameters
 592 (direction, interline spacing, altitude and speed). Altitude values are reported as specified during flight planning with some
 593 missions using Above Ground Level (AGL), while others used Above Mean Sea Level (AMSL) due to differences in mission
 594 planning and operational requirements. These original specifications are retained to accurately reflect acquisition parameters.
 595 Pulse repetition for the RIEGL Mini-VUX scanner is fixed at 100kHz. Flights cover multiple experimental plots: 4 & 5 (single
 596 flight), 6 (8 flights), 7, 8, 10, 15, and the Tower plot (two flights) within the Paracou Research Site. All listed flights are
 597 provided individually; users may merge flights covering the same plot if needed for analysis.

Census Plot ID	Date & Time (UTC)	Direction [°]	Interline [m]	Alt [m]	Speed [m s ⁻¹]	Pulse Repetition Rate [kHz]

598

599 **UAV-LS data processing**

600 All collected raw data underwent processing with standard tools. For VUX-1UAV data, this included processing
 601 recorded [global navigation satellite system](#) (GNSS) and base station data to flight trajectories with POSPac [Mobile](#)
 602 [Mapping](#) Suite 8.3 (Applanix, Richmond Hill, Ontario, Canada), laser waveform processing to discrete returns and geolocation
 603 in world coordinates with RIEGL RiProcess 1.8.6. For miniVUX-1UAV, waveform processing is performed online in the
 604 sensor. Point cloud processing and geolocation was performed with the CloudStation software (YellowScan, Montpellier,
 605 France), using the Strip Adjustment option. For all UAV-LS data, only points with a reflectance larger than -20 dB were kept
 606 for further processing. Points with reflectance smaller than -20 dB consist mainly of spurious points caused by water droplets
 607 under high humidity conditions ([Schneider et al., 2019](#)).

608

609 LiDAR point clouds were processed using the *LASTools* suite (rapidlasso GmbH). First, a 1-m resolution digital surface model
610 (DSM) was generated with **lasgrid** using the highest return within each cell. Ground points were then classified
611 with **lasground** (wilderness settings, 15-m step), and a 1-m digital terrain model (DTM) was derived from ground-classified
612 points using **las2dem**. Heights were normalized by subtracting ground elevation with **lasheight**, producing a set of height-
613 normalized point clouds. A 1-m canopy height model (CHM) was computed with **lascanopy**, retaining the maximum height
614 in each grid cell after removing noise and low-confidence classes. Finally, a point density map (1-m resolution) was created
615 using **lasgrid** with the *counter* option. This workflow produced consistent DSM, DTM, CHM, and density layers suitable for
616 subsequent ecological analyses. These UAV-LS datasets are provided in the **WGS84 coordinate reference system**
617 (**EPSG:4326**) and freely available via the Centre for Environmental Data Analysis (CEDA) with DOIs provided in section 5.
618 Data access.

619 **UAV-LS: FBRMS-02: Lopé, Gabon**

620 UAV-LS data was collected in June 2022, concurrently with TLS data acquisition at this FBRMS. Data was acquired using a
621 DELAIR DT26X drone platform equipped with a RIEGL miniVUX-1DL (Mcnicol et al., 2021) as seen in Fig. 11. This
622 platform differs from the one used at FBRMS-01: Paracou in that it is designed for large-scale data acquisitions (thousands of
623 hectares) and is capable of operating beyond the VLOS, with an average flight speed of 17 m s^{-1} (61 km h^{-1}). Flights were
624 conducted in perpendicular lines at a nominal altitude of 120 m above the ground surface, with an average flight line spacing
625 of 20 m (based on 70–80% overlap). Each one-hour flight covered approximately 120–200 hectares with an estimated point
626 density of 400 points per square metre. To obtain the required densities, several flights were conducted over the core plots
627 from different angles (depending on wind conditions) to maximise the diversity of viewing angles into the canopy.

629

630 **Figure 11:** UAV-LS acquisitions at FBRMS-02: Lopé using a fixed-wing system. This UAV employs a conventional take-off
 631 and landing (CTOL) procedure, with launch aided by a catapult (top). Once airborne, the UAV is controlled from a laptop
 632 connected to the UAV via an antenna (middle). The flight trajectory is corrected to centimetre precision using data collected
 633 from a static GNSS receiver placed within 10 km of the UAV operating area (lower left). Additional refinements and
 634 corrections are possible via ground control points located across the study area (lower middle), the positions of which are
 635 measured using a ‘rover’ GNSS receiver (lower right). Image originally published in McNicol et al. (2021).

636 **UAV-LS data processing**

637 Flight trajectories were reconstructed using GNSS/IMU measurements and adjusted with differentially corrected base station
638 data in Applanix POSPac software. The corrected flight paths and laser data were then integrated using the RIEGL software
639 package, RiPROCESS, to generate the initial three-dimensional point cloud. Residual trajectory errors—such as discrepancies
640 in GPS tracking and elevation—were corrected by using small buildings as reference points to refine the relative position and
641 orientation of individual flight lines and scans. Further adjustments were made using ground control points: square targets (1–
642 2 m²) composed of alternating black and white material arranged in a checkerboard pattern. Geometric accuracy refers to the
643 absolute positional accuracy of the final point cloud after these corrections, quantified by the residuals between LiDAR points
644 and surveyed ground control points. This process resulted in a LiDAR-derived point cloud with a geometric accuracy of 1.8 cm.
645 All elevation data were calculated as ellipsoidal heights (m) within the UTM 32S coordinate system. Each flight was processed
646 separately, and all datasets were merged prior to export. Subsequent point cloud processing was carried out using elements of
647 the lidR package (v3.1.0; Roussel et al., 2020). This UAV-LS dataset is freely available via the Centre for Environmental Data
648 Analysis (CEDA) with DOIs provided in section 5. Data acquisition characteristics can be found in Table 6.

649

650 **2.2.4 Airborne Laser Scanning (ALS)**

651 **Table 9:** Comparison of ALS acquisition characteristics for two ForestScan sites: FBRMS-01:Paracou, French Guiana and
 652 FBRMS-03: Kibili-Sepilok, Malaysian Borneo. These key flight and sensor characteristics can support alignment and
 653 comparability across sites.

ALS flight characteristics	FBRMS-01: Paracou, French Guiana	FBRMS-02: Kibili-Sepilok, Malaysian Borneo
Date	Nov 2019	Feb 2020
Area covered	10 km ²	27 km ² (Kibili-Sepilok) + 20 km ² (Danum Valley protected area) + 9 km ² (reduced impact logging area adjacent to Danum Valley)
Scanner	RIEGL LMS - Q780	RIEGL LMS - Q560
Platform	BN2 aircraft	Helicopter
Altitude	~900 m	~350 m (above forest canopy)
Speed	~180 km h ⁻¹ (50 m s ⁻¹)	~100 km h ⁻¹ (30 m s ⁻¹)
Scan angle	±30°	±30°
Pulse density	Min 15 pts m ² ; Mean 40 pts m ²	Mean 40 pts m ²
Overlap	80%	40%
CRS	EPSG:2972	EPSG: 32650

654

655 **FBRMS-01: Paracou, French Guiana**

656 ALS data were acquired over Paracou in November 2019. The data covers 10 km², including all experimental plots and areas
 657 covered by TLS and UAV-LS (see Fig. 1). During the same campaign, additional data was gathered over Nouragues Research
 658 Station in French Guiana. This supplementary data was collected using identical scanning characteristics (provided in Table
 659 9) and has been incorporated into the ForestScan data archive.

660

661 ALS data for Paracou are freely available via the Centre for Environmental Data Analysis (CEDA) with DOIs provided in
 662 section 5. Canopy height models for both Paracou and Sepilok are described in Jackson et al. (2024) and available at
 663 <https://doi.org/10.908679>.

664 **FBRMS-03: Kabili-Sepilok, Malaysia**

665 ALS data were acquired at Kabili-Sepilok in February 2020. This dataset includes LiDAR and RedGreenBlue (RGB) imagery
666 data collected from a helicopter over the Kabili-Sepilok Forest Reserve and an additional non-ForestScan site -Danum Valley
667 Forest Reserve. These areas were selected due to the availability of prior ALS data collected in 2013 and 2014. The complete
668 collection and processing details for these datasets are detailed in Jackson *et al.* (2024).

669

670 The point cloud data for this FBRMS are available in LAS (LASer) format, as well as RGB data summary rasters in .tif format.
671 The raster images were processed with LAStools using default parameters. Canopy Height Model (CHM), Digital Surface
672 Model (DSM), Digital Terrain Model (DTM), and pulse density (pd) data are also included. The RGB data are provided in
673 .jpg format and organised by flight date. The data was georeferenced using ground control points. This ALS dataset is freely
674 available via the Centre for Environmental Data Analysis (CEDA) with DOIs provided in section 5.

675 **3. Recommendations for aligning and matching datasets**

676 We provide data that are internally consistent in terms of pre-processing, geo-referencing, and exported in formats compatible
677 with open-source tools. Any further processing will depend largely on the intended application, such as individual tree analysis
678 or plot-level studies.

679

680 For TLS data, all point clouds within a single plot are co-registered into one unified point cloud. These are subsequently
681 processed into individual tree point clouds, to which quantitative structural models (QSMs) are fitted to estimate volume.
682 Datasets for FBRMS-01 and FBRMS-02 were acquired using a RIEGL VZ-400i equipped with GNSS RTK positioning.
683 However, as GNSS performance is often compromised beneath dense tropical canopies, positional accuracy for these datasets
684 should be interpreted with caution.

685

686 UAV-LS and ALS datasets are geo-referenced, with positional accuracy determined by IMU and GNSS measurements. These
687 measurements can introduce errors that manifest as height biases between individual flight lines. Although no such
688 discrepancies were observed in our data, a definitive assessment would require a rigorous comparison with ground control
689 points -a step we have not undertaken. These datasets have not been explicitly aligned or matched to one another. Alignment
690 is possible but requires manual identification of control points within each dataset, as noted above, should be undertaken only
691 if necessary for the intended application of the data.

692 **3.1 Matching TLS to census data: stem maps**

693 A key step in estimating AGB from tree-level terrestrial laser scanning (TLS) point clouds is the selection of wood density for
694 converting volume to mass. Wood density represents a significant source of uncertainty in the indirect estimation of AGB,

695 whether through allometry and census DBH, EO-derived canopy height, TLS-estimated volume, or other methods (Phillips et
696 al., 2019). If the censused trees in each plot can be matched to their TLS counterparts, literature estimates of species-specific
697 WD (or field-measured values, if available) can be used. In the absence of such a match, plot-level mean WD values are
698 employed, as is common in most EO-derived estimates that rely on large-scale allometric models (e.g. Chave et al., 2014).
699 Research by Momo et al. (2020), Burt et al. (2020), and Demol et al. (2021) has demonstrated that significant bias can occur
700 in TLS-derived AGB estimates due to within-tree WD variations when literature-derived species average WD values are used.
701 However, Momo et al. (2020) suggest there is sufficient correlation between vertical gradients and basal WD to allow for
702 empirical corrections.

703
704 While it is preferable to match TLS trees to census trees, this process is not straightforward and is currently only possible
705 manually (if at all) after TLS data acquisition and co-registration. Once registered, a slice through the TLS plot-level point
706 cloud can be generated, enabling the identification of individual trees from their stem profiles. This stem map can be provided
707 in hard copy or digital format (e.g., high-resolution PDF) to the census team, who can then revisit the plot, moving through it
708 in the same manner as during the census—starting at the plot’s southeast corner or 0,0 and moving up and down by 10 m
709 quadrants—annotating the TLS stem map with each tree census ID. This process can be conducted separately or as part of an
710 existing census but is best performed simultaneously or as soon as possible after TLS collection to minimise changes and
711 facilitate collaboration between TLS and census teams. Despite success with this approach in some plots (e.g., Gabon 2016),
712 experience has shown that significant understory, terrain variation, and/or changes and tree falls between census and TLS data
713 collection (e.g., ~2 years between census and TLS data collection for FBRMS-03 plots, and significant tree falls and changes
714 due to a storm between census and TLS data collection in FBRMS plot LPG-01 in Gabon) make this process very challenging,
715 particularly for smaller stems (in the 10-20 cm DBH range).

716 **3.2 Aligning TLS to UAV-LS data (and other spatial data)**

717 Through its accurate global registration via PPK processing, UAV-LS can be regarded as a high-quality geometric reference
718 for registration. For the purpose of comparison with accurate ALS data or satellite observations, a registration of TLS to the
719 UAV-LS point cloud is highly recommended. The integration of GNSS directly into TLS data collection now ensures that
720 registered plot-level point clouds are aligned within a global coordinate system. This significantly facilitates the co-registration
721 of TLS and UAV-LS point clouds, given that GNSS accuracy is typically within 1 metre. Historically, placing all LiDAR point
722 clouds within accurate global coordinate systems necessitated dedicated survey measurements of plot corners or TLS locations
723 via GNSS, a process often hindered by signal attenuation in dense forests. Consequently, GNSS surveying of plot corner
724 locations is not a standard component of forest census protocols, although it should be considered essential for plots intended
725 for EO calibration and validation purposes. The reduced cost of RTK GNSS equipment and its subsequent routine integration
726 into TLS workflows have made this more feasible, despite the challenges in obtaining fixed positions, and maintaining radio
727 link with a base positioned on a well-known point under deep forest canopy cover. While this may not benefit ALS directly,

728 UAV-LS is likely to serve as a valuable intermediary between TLS (and census data) and ALS. The requirement for global
729 GNSS positioning also extends to other spatial datasets.

730 **3.3 Aligning TLS and UAV-LS to ALS data**

731 Aligning ALS data with TLS and UAV-LS datasets presents significant challenges. Despite the use of high-quality GNSS
732 positioning, meter-scale geolocation discrepancies between sensors can occur. Co-locating LiDAR datasets acquired at
733 different scales -TLS, UAV-LS, and ALS- remains complex, with no standard or “turn-key” solution currently available.
734 Manual intervention is often required, and the approach varies by site and sensor combination. While plot-level AGB
735 estimation is relatively tolerant to these discrepancies, finer-scale applications (e.g., matching to tree-level census data) demand
736 more precise alignment. This can be partially addressed through manual co-registration using common tie points across
737 datasets.

738

739 Achieving meaningful alignment also depends on the internal characteristics of ALS point clouds. Acquisition parameters such
740 as point density, scan angle distribution, and footprint size influence comparability and should be controlled as far as possible.
741 Post-processing can regularise point density and scan angles within or across campaigns, improving consistency.
742 Homogeneous scanning geometry enables more stable structural metrics and enhances AGB prediction performance.
743 Similarly, parameters such as transmitted pulse power (which co-varies with pulse repetition rate) and flight altitude (affecting
744 footprint size and canopy penetration) should be standardised across acquisitions to minimise bias (Vincent et al., 2023). These
745 steps are critical for reducing alignment errors and ensuring robust comparisons between TLS, UAV-LS, and ALS datasets.

746 **4. Recommendations for data collection in FBRMS**

747 Building on this first case study, we make the following general recommendations for data collection of tropical forest plot
748 census, TLS, UAV-LS and ALS data for the specific application of estimating AGB and upscaling to EO estimates. These
749 recommendations follow from the CEOS LPV AGB protocol and subsequent requirements identified for the GEO-TREES
750 initiative.

751

- 752 **Consistent data acquisition and processing:** in order to facilitate the comparison of AGB estimates between sites,
753 dates, teams, etc. care should be taken to collect and process data as consistently as possible. This might seem obvious
754 but is particularly important as the use of TLS and UAV-LS for AGB estimation (and even ALS in some cases) are
755 currently primarily research-led (as opposed to fully operational). As new methods and tools are developed, including
756 newer versions of existing software, care should be taken to ensure backwards compatibility of the resulting AGB
757 estimates. This means either re-processing older data, or at the very least, some form of cross-comparison of original
758 and new methods. In our experience, listed below are some of the areas where care is needed to ensure data
consistency and reduce bias and uncertainty:

759

- **TLS data acquisition** - comparison between sites and plots is made much easier by using the same census, TLS, UAV-LS and ALS data acquisition and processing protocols. Even within the forest plot census community there are slightly different protocols and processes between different plot networks. This is even more variable for different sources of LiDAR data. We note that much of the TLS work in tropical forests aimed at volume reconstruction and AGB estimation has been carried out with RIEGL VZ series TLS instruments. We make no comment as to what is ‘the best’ instrument - there are various cost/benefit trade-offs to be made. Equipment has to be robust to withstand tropical forest work (and humidity). LiDAR range needs to be in the 100s of metres to ensure points are returned from tall canopies. Phase-shift TLS systems can be light and have very rapid scan rates, but suffer from ‘ghosting’ of multiple returned hits along a beam path. Mobile Laser Scanning (MLS) systems offer rapid coverage, and require minimal input for registration by using simultaneous location and mapping (SLAM), but tend to have lower range and precision due to the uncertainty in absolute location resulting from SLAM. It is likely that these systems will become more powerful and precise, offering a possible alternative to static tripod-mounted TLS in the future for AGB applications. Specific issues to consider are TLS power. For example, the RIEGL VZ-400 and newer VZ-400i systems (both used here) have different recording sensitivities i.e. down to -30 dB for the newer VZ-400i, whereas the VZ-400 only recorded to -20 dB. This can have a significant impact on the number of returns, particularly from further away and higher in the canopy and should be taken into consideration when comparing results between older and newer TLS instruments. Choices are also possible in terms of power settings: lower power settings reduce scan times & extend battery time, but also significantly reduce the quality of resulting point clouds, particularly higher in the canopy. TLS data were collected using a pulse repetition rate (PRR) of 300 kHz on RIEGL VZ-400 and VZ-400i scanners, trading longer scan times for a fixed angular resolution to maximise coverage at the tops of tall trees. In the RIEGL configuration, PRR and emitted laser power are intrinsically linked: increasing the PRR reduces the available power, which in turn decreases the maximum range of the scanner. At very high PRR settings, this reduction in range means that the tops of tall trees may not be captured effectively. Therefore, selecting a lower PRR (300 kHz) ensures sufficient power and range to cover the full canopy height of forests, while maintaining the desired angular resolution. However, recent work by Verheltz et al. (2024) suggests that using lower power, but with higher angular resolution, can achieve better coverage in tall forests for the same scan duration (3 mins per scan). More generally, comparing measurements made with scanners of varying power, sensitivity, resolution etc. will compound uncertainties (particularly biases) in the resulting estimates of AGB and so should be avoided or minimised as far as possible. This is particularly important for large-scale site-to-site comparison required for EO biomass product cal/val (e.g. for global FBRMS comparisons).
- **TLS processing** - broadly, TLS data acquisition and processing in tropical forests has gradually converged towards something of a consensus, albeit this is still an active area of research and will vary depending on

793 the team, site and application. Specific issues to consider are the way in which trees are extracted from plot-
794 scale point clouds. Currently, the most accurate method for doing this is by manual cleaning of each tree
795 using a tool such as CloudCompare (CloudCompare Development Team, 2025). However, this is a time-
796 consuming and somewhat subjective process that is not fully replicable - different people will produce
797 slightly different results. Automated pipelines using machine learning/deep learning (ML/DL) offer a more
798 rapid and repeatable approach (e.g. Krisanski et al., 2021; Wilkes et al., 2023), however, their resulting tree
799 extraction accuracy is harder to assess given that the 'true' structure of trees is unknown. Manually-extracted
800 trees can be used to assess automated tree extraction accuracy, as well as forming the training data to enable
801 improvements in the underlying ML/DL approaches. Developing locally-trained / optimised ML/DL models
802 is likely to improve this approach further. Moving from individual tree point clouds to volume estimates it
803 is also important to use consistent QSM-fitting approaches. For example, there are systematic differences
804 between older and newer versions of TreeQSM, currently the most widely-used QSM fitting software
805 (Demol et al., 2024; Raumonen et al., 2013). Quantifying the uncertainty in tree-level estimates of volume
806 will depend on this processing chain, which will then determine the plot-level uncertainty when upscaling.

807 • **UAV-LS acquisition and processing** - due to the wide range of platforms and LiDAR payloads being used
808 (as well as local UAV and safety regulations), there is currently little consensus in terms of both acquisition
809 and processing of UAV-LS data. There are a wide range of flight choices (particularly altitude), instrument
810 settings (scan angle), and survey systems (overlap, duration, etc.) that are a function of platform
811 performance, cost, etc. The impact of some of these choices is discussed in Brede et al. (2022b) where the
812 benefits of higher power, multiple returns and overlapping flights in detecting canopy structure are
813 highlighted. UAV-LS is not a like-for-like replacement for TLS, thus, the ability to compare these two
814 different sources of LiDAR data will be facilitated by accurate geo-location (see above). This can be
815 achieved by using ground targets with surveyed locations that can be identified in the UAV-LS data (e.g.
816 reflective sheets/tarps, umbrellas, commercial UAV targets etc). This presupposes that there are sufficient
817 gaps in the canopy for targets to be seen, which is not always true. During data collection attention should
818 be paid to also either have access to GNSS observables from permanent base stations (e.g. CORS network)
819 or collect observables with a temporary base station (e.g. Emlid Reach RS+ or RS2). A base station should
820 be positioned less than 15 km away from the survey area. An important consideration for UAV-LS data
821 collection is whether visual line of sight VLOS needs to be maintained, i.e. visibility of the platform by the
822 pilot during the whole mission. If so, this can impact the choice of take-off, flight plan, etc. which in turn
823 may influence the choice of platform. Fixed-wing platforms have a much greater area coverage and flight
824 duration than VTOL platforms, but by necessity, must operate beyond VLOS (BVLOS). They also require
825 far more space to take off and land than VTOL platforms.

826 ● **ALS acquisition and processing** - while ALS has been used operationally for forest applications for several
827 decades, its application for AGB estimates specifically is still less well-defined. In particular, this is true
828 when considering tree-scale rather than plot-level estimates. Practically, ALS surveys are almost always
829 outsourced (from the plot PIs, census and TLS, UAV teams) to commercial or agency (e.g. NASA, ESA,
830 NERC) providers. In the former case, there may be limited input from the end user over the platform,
831 instrument and acquisition parameters, or the way in which the data are processed to the resulting final
832 delivery. In ESA, NERC, NASA acquisitions, there tends to be more input from the users, but there may be
833 other restrictions in terms of when and where flights can be made. We recommend a pulse density of 10 m^{-2}
834 or higher and a swath angle of +/-15 degrees or smaller. Most importantly, consistency over time of the
835 other acquisition parameters should be sought to enable meaningful temporal analysis of ALS point cloud.
836 In most cases, the 3D point cloud will be processed to generate a 2D canopy height model for further analysis.
837 This post-processing can have important effects on the results, we therefore, recommend users follow a
838 standardized procedure such as Fischer et al. (2024).

839 ● **Accurate (cm-scale) GNSS locations for 1ha FBRMS plot corners (or at the least the nominal origin 0, 0
840 coordinate for each plot):** this makes comparison and merging of any subsequent measurements much easier. It is
841 important to note that this is not a standard requirement of forest census measurements and requires specialist
842 surveying equipment e.g. GNSS RTK base station + rover configuration. It is also challenging under heavy forest
843 cover. Given that such setups are required (ideally) for TLS and UAV-LS, plot corner surveying is potentially best
844 carried out by these teams.

845 ● **Linking TLS trees to their census counterparts:** ideally, a permanent $10 \times 10\text{m}$ subplot grid would be established
846 within each 1 ha forest plot. Census teams can then follow the same chain sampling pattern used in TLS data collection
847 (see Figure 2.1.4b & c) and identify the tree IDs found within each $10 \times 10 \text{ m}$ quadrants as they move through the
848 plot. However, placing a $10 \times 10 \text{ m}$ sub-grid is not always straightforward (or even desirable) as it may require rebar
849 posts, which can be expensive and are likely to be removed or damaged by e.g. elephants in West African plots
850 particularly. An alternative approach is to label some trees with temporary numbered QR-type markers that can be
851 read automatically from the lidar point cloud data. The markers can be printed on A4 waterproof paper, attached to
852 trees with known census ID, and then identified in the TLS data using a tool such as qrDAR (Wilkes et al., 2017). If
853 the 20 or so largest trees are labelled in this way, distributed across a 1 ha plot, this makes subsequent tree matching
854 between census and TLS data much easier as there are known ‘anchor trees’ for the survey team to work from.

855 **5. Data Access**

856 This paper presents 30 datasets, comprising LiDAR and tree census data for all three ForestScan FBRMS. All datasets are
857 archived and publicly accessible through established data repositories. LiDAR datasets, including TLS, UAV-LS and ALS are

858 freely available from the CEDA Archive (<https://archive.ceda.ac.uk>) under the ForestScan data collection
859 (<https://dx.doi.org/10.5285/88a8620229014e0ebacf0606b302112d>; Chavana-Bryant et al., 2025b). This collection serves as
860 an umbrella repository linking all individual LiDAR datasets by site and acquisition type. All tree census datasets are provided
861 as curated data packages made available by the ForestPlots consortium and the French Agricultural Research Centre for
862 International Development (CIRAD) open-access portal.

863
864 Tree census data packages for all three FBRMS are made available via two archival platforms: the CIRAD DataVerse portal
865 for French Guiana (<https://dataVERSE.cirad.fr/dataset.xhtml?persistentId=doi:10.18167/DVN1/94XHID>; Derroire et al., 2025),
866 while Gabon and Malaysian Borneo data are available through ForestPlots.net (https://doi.org/10.5521/forestplots.net/2025_2;
867 Chavana-Bryant et al., 2025a). An additional census dataset for a non-ForestScan plot at FBRMS-01 is included in Table 10
868 and made available via the CEDA archive.

869
870 Both tree census archival platforms operate under a fair use policy, governed by the Creative Commons Attribution-
871 NonCommercial-ShareAlike 4.0 International Licence (CC BY-NC-SA 4.0) (see <https://forestplots.net/en/join-forestplots/working-with-data> and <https://dataVERSE.org/best-practices/dataVERSE-community-norms>). These policies reflect a
872 strong commitment to equitable and inclusive data collection, funding, and sharing practices, as outlined in the ForestPlots
873 code of conduct (<https://forestplots.net/en/join-forestplots/code-of-conduct>). Tropical forest plot census data provide unique
874 insights into forest structure and dynamics but are challenging and often hazardous to collect, requiring sustained investment
875 and logistical support in remote regions with limited infrastructure. A persistent challenge to equitable research is that those
876 who collect these data are often least able to exploit the resulting large-scale datasets. This issue is particularly acute in the
877 context of commercial data exploitation, including by artificial intelligence and large-scale data mining enterprises. To address
878 this, the ForestPlots community has developed data-sharing agreements that promote fairness and inclusivity, as detailed in de
879 Lima et al. (2022).

880
881 Access and citation details for all ForestScan datasets are organised by site in Tables 10, 11, and 12 for FBRMS-01: Paracou,
882 French Guiana, FBRMS-02: Lopé National Park, Gabon, and FBRMS-03: Sepilok-Kabili, Malaysian Borneo, respectively.
883 Each table provides the specific data type, acquisition date, license type and citation format including DOI and URL for each
884 individual ForestScan dataset.

885
886
887 **Table 10:** Dataset type, acquisition date, license type, and citation format including DOI and URL details for LiDAR (TLS,
888 UAV-LS and ALS) and tree census datasets available for FBRMS-01: Paracou, French Guiana. When using any of the
889 ForestScan datasets, this paper must also be cited.

898 **6. Author contributions**

899 All authors provided input towards the writing of this manuscript.
900 C.Ch.-B. wrote the manuscript with significant input from M.D.
901 C.Ch.-B. developed the TLS data processing pipeline.
902 C.Ch.-B. collected, cleaned, processed and curated TLS data.
903 C.Ch.-B. developed the data repositories and ensured data integrity with support from M.D., the CEDA data management team
904 and the ForestPlots and DataVerse database management teams.
905 P.W. developed the TLS data processing pipeline, assisted in the collection of TLS data in FBRMS-02: Lopé, Gabon and its
906 processing.
907 W.Y. developed the TLS data processing pipeline, assisted in the collection of TLS data in FBRMS-01 Paracou, French Guiana
908 and its processing.
909 A.B., and T.J. collected TLS data in FBRMS-03: Kibili-Sepilok, Malaysian Borneo.

910 H.O.M.N. and L.M. provided field logistics and assisted in the collection of TLS data in FBRMS-02: Lopé, Gabon
911 L.S. and V. D. helped collect TLS in FBRMS-02: Lopé, Gabon.
912 K.A., S.N. & A.N. provided logistics and research permit support for FBRMS-02: Lopé, Gabon.
913 P.V. assisted in the processing of TLS data and developing the TLS2trees Processing Scripts.
914 A.C.B. collected census data in FBRMS-01 Paracou, French Guiana and in FBRMS-02: Lopé, Gabon with assistance from
915 D.L.M.C.
916 V.M., P.D, H.O.M.N. and K.J collected the field census data for LPG-01
917 N.L., P.D., H.O.M.N. and K.J. collected the field census data for OKO-01, OKO-02 and OKO-03 in Lopé, Gabon.
918 T.J., D.C. and G.V. planned and funded the ALS data collection in FBRMS-01, Paracou French Guiana.
919 T.J. & D.C. planned and funded the ALS data collection in FBRMS-03, Kabili-Sepilok, Malaysian Borneo.
920 I.M.M. arranged, collected and processed the UAV-LS data collected over FBRMS-02: Lopé, Gabon.
921 B.B., A.L. and H.B. collected, cleaned, processed and curated TLS and UAV-LS data collected at Paracou, French Guiana.
922 N.B., G.V. collected, cleaned, processed and curated TLS and UAV-LS data collected at Paracou, French Guiana.

923 **7. Competing interests**

924 A.B. is an employee and/or shareowner of Sylvera Ltd. All other authors declare that they have no conflict of interest.

925 **8. Acknowledgements**

926 We are indebted to the long-term work of many researchers in funding, establishing and maintaining the field plots that were
927 used in this study. It is not possible to carry out meaningful cal/val measurements of tropical forest biomass for earth
928 observation studies without the logistical support and expertise of the plot PIs and their teams. We thank Dr Noreen Majalap
929 for logistical and research permit support in FBRMS-03, Kabili-Sepilok, Malaysian Borneo. We also thank the Sabah
930 Biodiversity Council for their support with airborne laser scanning data collection in Kabili-Sepilok, access license number:
931 JKM/MBS.1000-2/2 JLD.9 (122). We thank Esther Conway and her team for their outstanding support in developing the
932 ForestScan CEDA dataset collection. We thank Dr Aurora Levesley and Gaëlle Jaouen for their generous support in developing
933 the ForestPlots and DataVerse tree census data packages. Specific data collection activities were funded by the European Space
934 Agency under ESA/ contract No. 4000126857/20/NL/AI. Work in French Guiana benefited from the Investissement d'Avenir
935 grants of the ANR, France (CEBA: ANR-10-LABX-0025). M.D., P.W., C.Ch.-B., W.Y. acknowledge capital funding for TLS
936 equipment from UCL Geography and the NERC National Centre for Earth Observation (NCEO). T.J. and D.C. acknowledge
937 the funding for ALS data collection over FBRMS-01 Paracou, French Guiana in 2019 and FBRMS-03: Kabili-Sepilok,
938 Malaysian Borneo during February 2020 as part of a NERC project grant (NE/S010750/1). I.M.M. was partly funded by a

939 European Research Council Starting Grant (757526) awarded to E.T.A.M. Work in Lopé was supported by core funding from
940 Total Gabon and the EU-ACP ECOFAC VI grant to the Gabon National Parks Agency for logistics, staff and site operations.
